*Hab.* Philippines.

(1266) *Nanina Borneensis*.

Shell obliquely perforate, depressed, rather thin, decussated by distinct striae of growth and numerous oblique impressed lines, dark fulvous; spire scarcely raised, blunt; suture bordered with an impressed line; whorls four, little convex, increasing rapidly, the last one marked at the periphery with a blackish band, which is dilute towards the centre; more convex beneath and irregularly radiated with chestnut streaks; aperture oblique, large, transversely lunate-oval, nearly

within, with the band translucent; peristome simple, sharp, with the columellar margin reflected into a short triangular lamina, which covers half the umbilicus. Height 25, greatest breadth 52, least breadth 42 mill. (*Pfr.*)

*Helix Borneensis*, *Pfr.* in *Proc. Zool. Soc.* 1849 p. 127; *Mon. Suppl.* 70.

*Hab.* Borneo.

This species in shape, size and habitus greatly resembles *N. sagittifera*; but its sculpture is different, its spire less raised, its whorls increasing rather slowly, and its aperture is larger and more oval.

(1267) *Nanina ovum*.

Shell slightly perforated, globosely, depressed obliquely striated and irregularly wrinkled, slightly decussated with impressed lines, very close at the apex, remote and irregular on the last whorls, obtusely keeled, entirely deep fulvous, or ornamented with a pale band above the keel, and a purplish-black band beneath the keel; suture channeled; whorls five, tumid above, the last excavated at the columella: aperture lunate-elliptical, inside bright, milky; peristome simple, thick, dextral margin archedly dilated. Lat. maj. 115, min 80, alt 70 mill.

(1268) *Nanina nobilis*.

Shell narrowly umbilicate, depressed, rather turbinate, solid, striated, slightly decussated with impressed spiral and oblique lines, fulvous; spire little raised, shortly turbinate; whorls six, scarcely convex, the last surrounded in the middle with a raised, blunt ridge, below which is a dark chestnut-coloured band, which is diffuse and vanishes towards the umbilicus; aperture large, little oblique, broadly lunate, pearly within; peristome simple, straight; columellar margin reflected into a short triangular lamina near the umbilicus. Height 30, greatest breadth 53, least breadth 45 mill. (*Pfr.*)

*Helix nobilis*, *Pfr.* in *Proc. Zool. Soc.* 1849, p. 127; *Ik.* n. 771. t. 125. f. 1. 2.; *Mon. Suppl.* 69.

Whitish, with a single narrow peripheric band, beneath which the last whorl is of a pale violaceous colour.

*Helix obliquata*, *Reeve, Conch. Icon.* n. 384 t. 74.

*Hab.* Borneo; the variety from the Philippine Islands (?).

(1269) *Nanina Mulleri*.

Shell obteetly perforated, convexly orbiculate, slightly keeled, solid, fulvous, darker beneath, marked with a broad red band beneath the keel; suture linear; whorls four and a half, rapidly increasing, the highest plane, minutely rugulose, reticulated, the last convex towards the aperture irregularly malleately rugose; aperture lunate-oval; peristome simple, upper margin slightly inflected, columellar a little expanded, covering the perforation. Lat. maj. 39 min. 33, alt 23 mill.

(1318) *Ariophanta trifasciata*.

Shell sinistral, perforate, rather conoidally depressed, striate, decussated with crowded spiral lines, little shining, fulvous-whitish, with three chestnut-coloured bands, one of which runs along the suture, the second above, and the third below the periphery of the last whorl; spire rather conoidally raised; whorls five, scarcely convex, regularly increasing; the last one keeled, rather rounded anteriorly, deflected, convex beneath;

## MOLLUSCA.

aperture small, very oblique, regularly lunate; peristome simple, sharp, with the margins distant, columellar margin declivous, rather thickened, shortly reflected near the perforation. Height 14, greatest breadth  $25\frac{1}{2}$ , least breadth 22 mill. (*Pfr.*)

*Hab.* Neilgherries, South India. (*Jerdon*).

(1326) *Vitrina præstans*, *Gould*. Mr. Mason errs in saying that this is the largest species of the Genus. In 1836 I described *V. gigas*, which is  $1\frac{3}{8}$  inch in greatest diameter. Tenasserim Provinces.

(1327) *Vitrina gigas*.

Shell rather solid, depressed, with arched striae, obsoletely and irregularly decussated by spiral lines, olive-horny; spire minute, level; suture impressed; whorls two and a half, rapidly increasing, the last slightly depressed above, outline rounded, base narrow; aperture very oblique, large, regularly transversely oblong, slightly callous inside, margins nearly contiguous, upper and lower rather straight, columellar slightly arched. Lat. 30 by 18, alt 13 mill.

*Vitrina gigas*, *Benson in Journ. As. Soc.* v. 350.

350. *Prf. Mon. Helic.* ii. 496. n. 10.

*Hab.* Bengal.

(1328) *Vitrina cassida*.

Shell depressed, thin, slightly striated, scarcely shining, not quite diaphanous, with the periphery ovate, pale greenish horn-coloured; spire very shortly conoidal, suture slightly bordered; whorls nearly five, enlarging rapidly, the last rounded, somewhat depressed, broad beneath and impressed in the centre; aperture very oblique; lunarly ovate, pearl-shining within; peristome simple, upper margin a little dilated forwards,

## MOLLUSCA.

slightly callus. Height 12, greatest breadth 26, least breadth 22 mill. (*Pfr.*)

*Vitrina cassida*, *Hutt Pfr. Mon.* ii. 497, n. 12. *Suppl.* 2; *Icon.* t. 2, f. 3, 5.

*Hab.* Simla, Western Himalaya.

(1329) *Vitrina præstans*.

Shell depressed semiglobose, thin, striatulate, slightly decussated by rather distant spiral lines, scarcely shining, pale horny; spire not prominent; suture very lightly impressed; whorls three, rapidly increasing, the last convex above, outline subdepressed, base rather wide; aperture very oblique, subtriangular semioval; peristome simple, slightly inflected, margins approximate, columellar receding, very arched. Lat. maj. 20, min. 16, alt. 10 mil.

*Vitrina præstans*, *Gould in Post. Journ.* iv. 456, t. 24 f. 2.

*Pfr. Mon. Helic.* ii. 497. n. 13.

*Hab.* Tavoy, Birmah.

(1330) *Vitrina monticola*.

Shell depressed, thin, striatulate, shining, pellucid, lutescent-horny; spire plane, scarcely prominent in the middle; suture lightly impressed; whorls four, rapidly increasing, nearly level, the last depressed, not descending; aperture oblique, rounded-lunar; peristome simple, margins connivent, united by a very thin callus, arched-dilated above in front, the columellar forming an obtuse angle with the basal, Lat. 18 by 14, alt  $7\frac{1}{2}$  mill.

*Vitrina monticola*, *Benson, M.S.S.*

*Pfr. in Proc. Zool. Soc.* 1848; *Mon. Helic.* ii. 497; *Icon.* t. 2. f. 6-8.

*Hab.* Bengal; Landour; Himalaya; Almorah.

(1331) *Vitrina Bensoni*.

Shell slightly depressed, thin, striatulate, bright, pellucid, pale horny; spire scarcely elevated, obtuse; suture impressed, slightly margined; whorls three and a half, slightly convex, the last rather depressed, rounded at the periphery, wide at the base; aperture oblique, lunate-sub-oval; peristome simple, slightly inflected, margins connivent, rather dilated in front above, columellar receding, much arched. Lat. maj. 12, min  $9\frac{1}{2}$ , alt 6 mill.

*Vitrina Bensoni*, *Pfr. in Proc. Zool. Soc.* 1848. *Mon. Helic.* ii. 497, n. 14.

*Hab.* E. Indies.

(1332) *Vitrina birmanica*.

Shell depressed, transversely ovate, very thin and smooth, bright, luteous-green; spire scarcely elevated; whorls four, rapidly increasing, scarcely convex, disunited at the impressed suture, the last subplanulate at the base; aperture very oblique, widely lunate-oval; peristome acute dextral margin arched in front. Lat. maj  $9\frac{1}{2}$ , min.  $7\frac{3}{4}$ , alt  $4\frac{2}{3}$  mill.

*Vitrina birmanica*, *Phil. in Zeitschr. f. Mal.* 1847, p. 65.

*Pfr. Mon. Helic.* ii. 498.

(1333) *Vitrina gruneri*.

Shell globose depressed, very smooth, dull, olive horny; spire scarcely raised; suture white-margined; whorls three and a half, slightly convex, the last rather depressed; aperture very oblique, lunate oval; peristome simple, margins connivent, columellar arched, sub inflected, Lat. maj. 8, min 6, alt 5 mill.

*Vitrina Gruneri*, *Pfr. Symp.* iii, 81; *Mon. Helic* ii, 498.

*Hab.* Arabia.

(1334) *Vitrina baccata*.

Shell small, thin, fragile, diaphanous and pale; whorls apparently only one, or at all events the body whorl may be said to constitute the whole shell, aperture nearly circular, lips scarcely interrupted slightly thickened and partially reflected, surface of the shell polished, finely striated by minute lines of growth, and ornamented with longitudinal bead like lines or strings of minute bubbles, which can be seen only under a strong lens, upper side depressed, flattened, under side rounded, ventricose. Length  $1\frac{1}{2}$  line. (*Hutton*.)

*Vitrina baccata*, *Hutton in Journ. As. Soc.* July 1809, p. 650.

*Pfr. Mon. Suppl.* 2.

*Hab.* Melnandeh, between Kopik Pass and Candahar, Afghanistan,

(1335) *Vitrina Cumingi*.

Shell depressed globose, very thin, finely striated, bright, whitish horny; spiral very short, obtuse; suture smooth, bordered by an impressed line; whorls four, scarcely convex, the last inflated, subdepressed, zoned in the middle by a rufous line; aperture rather oblique, lunate-rounded; peristome simple, margins remote, columellar subvertical, slightly arched, rather reflected above, resembling a punctiform perforation, scarcely arched above in front. Lat. maj. 20 min. 17, alt. 12 mill.

*Vitrina Cumingi*, *Beck, M.S.S.*

*Pfr. in Proc. Zool. Soc.* 1848; *Mon. Helic.* ii 498 n. 17, *Icon.* t. 3. 2. f. 1, 2.

*Hab.* Bohol, Philippines.

(1336) *Vitrina bicolor*.

Shell subglobose, thin, rather smooth, very bright, whitish pink; spire short, convex, obtuse; suture impressed; whorls three and a half, rapidly increasing, the last inflated, hyaline in front, rather narrow at the base, membranous margined; aperture scarcely oblique, lunate-rounded; peristome very thin, dextral margin regularly rounded, columellar receding, much arched. Lat. maj. 18, min. 14 alt. 10 mill.

*Vitrina bicolor*, *Beck, M.S.S.*

*Pfr. in Proc. Zool. Soc.* 1848; *Mon. Helic.* ii. 499.

*Hab.* Guimaras, Philippines.

(1337) *Vitrina guimarasensis*.

Shell depressed-sensiglobose, thin, striatulate,

subdiaphanous, greenish-pink; spire rather small, slightly elevated; suture margined; whorls scarcely four, nearly level, very rapidly increasing, the last inflated, subdepressed; aperture oblique, lunate-subcircular, as high as wide, slightly pearly within; peristome very thin, dextral margin regularly arched, columellar receding, much arched. Lat. maj. 15, min.  $11\frac{1}{2}$  alt 8 mill.

*Vitrina guimarasensis*, *Pfr. Proc. Zool. Soc.* 1848; *Mon. Helic.* ii 499.

*Hab.* Guimaras, Philippines.

(1338) *Vitrina Beckiana*.

Shell depressed-globose, circuit oval, very thin, striatulate, pellucid, bright, very pale rubelline-horny; spire moderate, short, obtuse; whorls nearly four, very slightly convex, rapidly increasing, the last subdepressed, wide at the base; aperture rather oblique, lunate rounded, wider than high; peristome simple, margins remote, regularly arched above, columellar slightly reflected above, receding at the base, much arched. Lat. maj. 16, min. 13, alt. 8 mill.

(1349) *Shells of Birmah and the Tenasserim Provinces.* By W. THEOBALD, Junior.

Mr. Theobald remarks as follows:—In the present paper it is my intention to give a sketch of the distribution of the land and fluviatile shells

been observed, in the hope that my notes may prove a not uninteresting addition to our previous knowledge of the subject, and shew by the great addition now made to the list of known species, how much yet remains to be done in this department of Natural History.

The names used are with scarcely an exception those furnished by Mr. Benson, who has described many of the new species in the *Annals and Magazine of Natural History* for 1857 though many still possess merely MSS. names, which, together with the new species described from specimens furnished by me, I have indicated in the following list, by asterisks (\*).

On my first communicating with Mr. Benson, he informed me that but twenty-three species of land shell were authentically known from the Tenasserim Provinces. Of these, four species, which escaped my notice, may here be mentioned to complete the list up to the present time, viz.

*Vitrina Birmanica*, Philippi.

*Bulinus moniliferus*, Gould.

*Cyclophorus perdix*, Sav.

*Leptopoma Birmanum*, Pfr.

*Vitrina Draparnaud*.

49. *V. Birmanica Philippi*, was not met with by me.

*Cryptosoma* (Theobald) *Vitrina* Præstans.

Gould. Moulmein.

*Vitrina*. Manantoddy.

*Vitrina gigas*. Sylhet.

(1350) *Helicarion aperta*.

Shell much depressed, slightly convex above, wide open at the base, smooth, subopaque, greenish-white; spire minute, lateral; suture smooth; whorls two and half, slightly convex, very narrow at the base, wide open, the last very large, smoothly vaulted; aperture horizontal, ear-shaped, open to the apex; peristome quite simple. Lat. maj. 11, min. 8, alt. 3 mill.

*Vitrina aperta*, Beck. MSS.

*Pfr. in Proc. Zool. Soc.* 1848; *Mon. Helic.* ii. 502.

*Hab.* Luzon, Philippines?

(1351) *Helicarion Ceylanica*.

Not described

*Vitrina Ceylanica*, Beck. *Index*, 2. n. 12; *Mus. R. O.* viii. t. 1. f. 3.

*Pfr. Mon.* ii. 503; *Id.* t. 6. f. 34-38.

*Hab.* Ceylon.

(1352) *Helicarion irradians*.

Shell depressed, with the periphery ear-shaped, thin, with crowded, arcuate, radiating impressed lines, obsoletely decussated with irregular spiral striae, diaphanous, scarcely shining, of a cinnamon horn-colour above; spire small, raised into a slight papilla; suture impressed, bordered; whorls nearly four, rather flat, enlarging rapidly, the last depressed, more convex beneath; aperture very oblique, lunate, nearly circular; peris-

regularly arched. Height  $3\frac{1}{2}$ , greatest breadth 184, least breadth 14 mill. (*Pfr.*)

Animal brown—*B. M.*

*Vitrina irradians*, *Pfr. in Proc. Zool. Soc.* 1851, *Mon. Suppl.* p. 3.

*Hab.* Ceylon.

*Asiatic animal unknown perhaps Vitrinae.*

(1353) *Helicarion papillata*.

Shell depressed, thin, nearly smooth, bright, pellucid, pale flesh-coloured; spire nearly level, papillated in the middle; suture deeply impressed, margined; whorls three and a half, slightly convex, striatulate near the suture, the last depressed, sometimes sculptured with obsolete spiral lines, periphery rounded, base rather wide; aperture very oblique, ample, rounded-lunar, wider than high; peristome thin, upper margin dilated above, columellar receding, much-arched. Lat. maj. 10, min. 8, alt. 5 mill.

*Vitrina papillata*, *Pfr. in Proc. Zool. Soc.* 1848, *Mon. Helic.* ii. 502.

*Hab.* Luzon Philippines.

(1354) *Helicarion planulata*.

Shell much-depressed, subdiscoidal, nearly smooth, bright, flesh-coloured; spire nearly level; suture impressed; whorls three, very slightly convex, very rapidly increasing, the last depressed, narrow at the base; aperture very ample, very oblique, lunar, transversely dilated; peristome thin, upper margin dilated in front, columellar far receding, arched. Lat. maj. 11, min. 8, alt.  $4\frac{1}{2}$  mill.

*Vitrina planulata*, *Pfr. in Proc. Zool. Soc.* 1848; *Mon. Helic.* ii. 502.

Clausilia loxostoma.	
Benson.	Teria Ghat. (3 sp.)

*Clausilia Draparnaud.*

*C. insignis*, Gould.—Moulmein. Very rare. Tenasserim Valley. Not common.

*C. Philippiana*, Pfr.—Moulmein, Tenasserim Valley. Very common.

(1359) *Clausilia insignis*, Gould.—The species sent under this name is very distinct from the species from Malacca, which I have described in Ms. as *C. stylus*, and which I find in Mr. Cuming's collection under the name of *chinensis* from Java. Possibly this name may be intended for *cochin-chinensis*, Philippi, the description of which I have not seen, and which appears to be recognized as distinct by Pfeiffer, from *C. insignis*, Gould. In May 1847, in referring to the Mergui *Clausilia philippiana*, he says; "mit *C. insignis*, Gould, nahe verwandt," a circumstance which, however, I cannot well understand, as *C. Philippiana* has only six whorls, and the specimen of *insignis* sent has nine. *Clausilia insignis* differs altogether from *C. stylus* in its smooth sculpture, its greater ventricosity, more blunted apex, the form of the mouth and the number and disposition of the plica in the interior. Tenasserim Provinces.

## Family II. Limacidæ. Slugs.

*Planorbis Indicus*.

*Planorbis Indicus*, variety, Ceylon.

*Planorbis*, Fresh water tank shell. Ceylon.

There is a species of *Planorbis* or shell allied to *Planorbis* found here in pools of fresh water, being the only species of Singapore shell that is found solely in fresh water; the outer whorl is little more than a quarter of an inch in diame-

ter, aperture of the shell more diagonal than is usual in *Planorbis* so that when the animal moves on a plain surface the convex side of the shell is always uppermost whereas the animal of *Planorbis* is described as carrying its shell erect or with the diameter perpendicular; colour of the shell pale amber, no operculum, animal nearly black, mouth vertically cleft, no perceptible neck, (in the animal of *Planorbis*, the neck is said to be elongated) eyes at the base of two blunt tentacula in which also it differs from *Planorbis* which is commonly described and figured as having two subulate tentacula; the animal possesses in a considerable degree, the power of gliding through the water, apparently in search of food, with its shell entirely submerged and its smooth foot in close opposition with the surface of the water, locomotion being effected, by causing the flat part of the shell to act on the water in the manner of a fin, the head of the animal being at the same time directed forward so as to regulate its movements; the animal does not occupy so much as half the shell, and the remaining space frequently contains air, which the inhabitant has the power of expelling at pleasure.

(1360) *Cyclostoma pernobile*, Gould.—Pfeiffer notes this shell as a synonym of *C. aurantiacum*. Schumacher (nec Sowerby), a near ally of *C. perdix*, Sowerby, and places both shells in the Sub-Genus *Cyclophorus*, Montf Pfeiffer observes; "Ein prachtiges *Cyclostoma*, welches Hr. Dr. Philippi zugleich mit den oben (154) erwähnten von seiner Reise mitgebracht hat, bestätigt vollständig meine früher ausgesprochene Vermuthung, dass *C. pernobile*, Gould, von Tavoy, dieselbe, Art sey, welche Chemnitz abgebildet, und Schumacher *Annularia aurantiaca* genannt hat. Jenes ist in Mergui gesammelt worden

## MOLLUSCA.

leren Färbung, völlig der Beschreibung und Abbildung von Chemnitz, so wie auch der Beschreibung von (Gould zwar ist der Kiel an dem vorliegenden Exemplar um ein Geringes weniger schar, als bei der Abbildung von Gould) wir wissen aber wie veränderlich dieser character gerade bei dieser Gruppe ist, und so dürfte bei der Identität des Vaterlands kein Zweifel mehr über diese ausgezeichnete Art Statt finden, welche zwar von Muller und Chemnitz mit *C. volutus* zusammengeworfen wird, aber jedenfalls ihre spezifische selbständigkeit zu behaupten im stande ist." Tenasserim Provinces.

(1361) *Cyclostoma sectilabrum*, Gould.—Pfeiffer refers this shell, as well as *C. croceum*, to Guilding's Sub-Genus *Megalomastoma*. It is quite distinct from *C. croceum* which belongs besides to the Mauritius. Pfeiffer says under the head of *Cyclostoma croceum*. "die von Gould ausgesprochene Vermuthung dass die Art mit seinem *C. sectilabrum* zusammenfallen werde, sich wohl als ungegründet erweisen dürfte, durchaus nicht vorhanden sind." Tenasserim Provinces.

### (1362) *Cyclostoma cuspidatum*.

Shell umbilicated, conoidal, acuminate, obliquely striated, marked with spiral lines; peristoma olivaceous-fuscous; spire elongated, slender, with the apex nipple-shaped; whorls 5, the first ones convex, the two last rather convex above, furnished with a single sidge, the last one convex beneath, keeled on the periphery, marked with three ridges beneath the keel and the umbilical ridge being crenulate; aperture very oblique, nearly circular, slightly angulated above; peristome thin, sharp, with the columellar margin slightly expanded; umbilicus middle-sized, deep, showing more than one whorl Opérculum? Height 4, greatest breadth 6, least br. 5 mill. (Pens.)

*Cyclostoma cuspidatum*, Benson in *Ann. and Mag. N. H.* viii. p. 189; *Pfr. Consp.* n. 466; *Pneum. Mon.* p. 313; *Id.* n. 407, t. 49, f. 21-23, *Hab.* The Neilgherries Mountains (Cerdon).

### (1363) *Cyclostoma? marginatum*.

Shell white subovate, wrinkled, perforate, with the whorls transversely margined and striated. (Chemn.)

*Turbo marginatus*, Chemn. *Conch.* ix. 2, p. 60, t. 123, f. 1076, a.

*Turbo limbatus*, Gmel. *Syst.* p. 3606, n. 105. *Cyclostoma murrhinum*, Menke. *Synops.* ed. ii. p. 39.

*Cyclostoma marginatum*, *Pfr. Consp.* n. 467; *Pneum. Mon.* p. 313.

*Hab.* Coromandel.

### (1364) *Cyclostoma sarritum*.

Shell subperforate, ovate-conic, furnished with numerous spiral lines, which are separated by

apex blunt, reddish; suture well impressed; whorls 4, very convex; aperture scarcely oblique ovate, forming  $\frac{2}{3}$  of the total length; peristome sharp, slightly expanded, with the margins distant, joined by callus, columellar margin angulated above. Length 2, breadth  $1\frac{1}{4}$  mill. (Bens.)

*Cyclostoma sritum*, Benson in Ann. and Mag. N. H. viii. p. 188, Pfr. Consp. n. 469; Pneum. Mon. p. 314.

Hab. Cherra Ponjee, India.

*Hypsclostoma*. Benson.

*H. tubiferum*, B.—Thaïet-mio. This singular little anostomatous shell was only met with at one spot on limestone rocks near the Coal mines, where it did not seem very rare.

(1365) *Cyclostomus Cuvierianus*.

Shell depressed, decussated by close-set longitudinal and more crowded spiral lines, grayish-fulvous; spire little raised; whorls 5-6, the upper ones convex, the following flattened, with one lamellar keel, the last one slightly convex above; furnished at its periphery with two distant sharp lamellar keels and numerous sharply-raised spiral ridges round the wide and open umbilicus; aperture oblique, rather circular, fulvous within; peristome white, broadly expanded, with the margins joined by rather thick callus, right margin showing two channels, columellar margin dilated and expanded above. Height 32, greatest breadth 64, least br. 54 mill.

*Cyclostoma Cuvieriana*, Petit, in Revue Zool. 1841, p. 134; Mag. Zool. 1842. t. 55.

*Cyclostoma Cuvierianum*, Reeve. Conch. Syst. t. 104, f. 14, t. 185, f. 24; Sow. Thes. n. 72. p. 115, t. 30, f. 218, 219; Philippi, Abbild. i. 5, p. 103, t. 1. f. 1; Pfr. Ic. n. 1, p. 9, t. 1, f. 1-4.

*Tropidophora Cuvieriana*, Pfr. in Z. f. M. 1847, p. 106, n. 1; Gray, Cat. Cycl. p. 37, n. 1.

*Cyclostomus Cuvierianus*, Pfr. Consp. n. 175; Pneum. Mon. p. 189.

Smaller, with the columellar margin of the peristome much dilated over the umbilicus; height 22, greatest breadth 37, least br. 32 mill.

Hab. Madagascar, and Nosibe.

(1366) *Cyclostomus formosus*.

Shell depressed trochiform, rather solid, furnished with three sharp keels, with the interstices decussated by raised spiral and more crowded transverse lines, fulvous-brownish, articulated with white on the keels and near the suture; spire stair-like, rather acuminate; whorls 5, flattened, the upper with one keel, the last one large, crowdedly spirally grooved below the third keel; umbilicus funnel-shaped; aperture diagonal, rather circular; peristome simple, with the margins joined by a thin emarginate callus, right margin expanded, showing two channels, columellar margin narrowly reflected. Height 23, greatest breadth 42, least br. 34 mill.

1849, p. 13; Moll. t. 2. f. 8, 9; Pfr. Ic. n. 231 t. 32, f. 1, 2.

*Tropidophora carinata* var., Gray Cat. Cycl. p. 39.

*Cyclostomus formosus*, Pfr. Consp. n. 275; Pneum. Mon. p. 190.

Hab. Madagascar.

(1367) *Cyclostomus cariniferus*.

Shell depressed, rather discoidal, trellised by distinct striae of growth and very numerous raised keels, and crowded spiral lines, fulvous-brownish, with a single darker band below the periphery; spire scarcely raised, slightly mucronate; whorls 5, moderately convex, enlarging rapidly, depressed along the suture; umbilicus wide; aperture little oblique, nearly circular; peristome fulvous, slightly thickened, shortly expanded, with the margins joined by a callus, which is produced upwards, columellar margin dilated, rather reflected. Height 17, greatest breadth 40, least br. 32 mill.

*Cyclostoma cariniferum*, Sow. Spec. Conch. f. 197, 198; Reeve. Conch. Syst. t. 185, f. 23; Sow. Thes. n. 69, p. 114, t. 25, f. 93; Pfr. Ic. n. 152, p. 144, t. 19, f. 13 15.

*Cyclostomus cariniferus*, Pfr. Consp. n. 277; Pneum. Mon. p. 191.

Smaller, with very numerous fainter keels, with the peristome reddish-orange-coloured; height 16, greatest breadth 36, least br. 28 mill.

*Cyclostoma spectabile*, Petit, in Journ. Conch. 1850, i. p. 46; t. 3, f. 2.

Hab. Madagascar, the variety from Nosse Faly, near Nosse Be (Guillair).

(1368) *Cyclostomus articulatus*.

Shell orbiculate-conoidal, solid, pale flesh-coloured, furnished with numerous keels, two or three of which are stronger and articulated with brown; spire broadly conoidal, with the apex rather blunt; whorls 5, moderately convex, rather angulated, increasing rapidly, the last one rather flattened below the peripheral keel, painted with a single brown band, grooved crowdedly and deeply, separated by a broader keel from the umbilicus, which is middle-sized, funnel-shaped, coarsely furrowed; aperture rather oblique, nearly circular, fulvous within; peristome slightly thickened, straight, with the margins joined by a short lunar-shaped indented callus, right margin sinuate above. Height 18, greatest breadth 28, least br. 24 mill.

*Cyclostoma articulata*, Gray in Griff. Anim. Kingd. t. 28, f. 1.

(1370) *Cyclostomus Abeillei*.

Shell orbiculate, rather trochiform, umbilicate, five keeled, transversely furrowed, whitish, with dark bands or yellowish spots; umbilicus deep; spire short, pointed; whorls 5: aperture rather circular; lips sharp, slightly reflexed. Height 16-17, breadth 20 mill.

*Cyclostoma Abeillei*, Grateloup, in *Act. Soc. Lin. Bord.* xi, p. 437, t. 3, f. 6.

*Tropidophora Abeillei*, Pfr. in *Z. f. M.* 1847, p. 106, n. 3; Gray, *Cat. Cycl.* p. 42, n. 19.

*Cyclostomus Abeillei*, Pfr. *Consp.* n. 280; *Pneum. Mon.* p. 193.

*Hab.* Madagascar.

(1371) *Cyclostomus modestus*.

Shell depressed, rather solid, slightly striate, with numerous spiral ridges and three sharper keels, brownish-white; spire flat; whorls 4, depressed, united by a channelled suture, the last convex beneath; umbilicus

# MOLLUSCA.

ristome white, with the margins approximate, joined by thin callus, right margin sinuate above, vaulted and expanded, angulated by the ends of the keels, columellar margin narrow, scarcely reflected. Height 9, greatest breadth 24, least br. 19 mill.

*Cyclostoma modestum*, Petit. in *Journ. Conch.* 1850, i. p. 50, t. 4, f. 2; Pfr. *Ik.* n. 333, t. 42, f. 16-18.

*Cyclostomus modestus*, Pfr. *Consp.* n. 281; *Pneum. Mon.* p. 193.

*Hab.* The Island of Abd-el Goury.

(1372) *Cyclostomus bicarinatus*.

Shell globose-conical, rather thin, closely but faintly spirally grooved, bicarinated, brownish gray; spire pyramidal, with the apex usually truncated; whorls 6, angulated, the last one girdled with two pale, acutely-raised keels, deeply spirally furrowed beneath; aperture rather vertical, nearly circular, shining blackish-blood-red within; peristome simple, expanded, purplish-blood-red, with the margins nearly continuous, columellar margin dilated above into a tongue shaped, vaulted lamina, which nearly altogether closes the umbilicus. Length 35, breadth of the penultimate whorl 23 mill.

*Cyclostoma bicarinatum*, Sow. *Thes.* n. 85, p. 120, t. 26, f. 121; Pfr. *Ik.* n. 147, p. 139, t. 19, f. 1-3; Desh. *Traité. elem. Conch.* t. 82, f. 1, 2.

*Tropidophora bicarinata*, Pfr. in *Z. f. M.* 1847, p. 106, n. 9.

*Tropidophora tricarinata* var., Gray, *Cat. Cycl.* p. 39.

*Cyclostomus bicarinatus*, Pfr. *Consp.* n. 284; *Pneum. Mon.* p. 165.

Smaller, with the umbilicus rather open; length 24, breadth 17 mill.

*Hab.* Madagascar.

(1373) *Cyclostomus tricarinatus*.

Shell top-shaped, acuminate, pale with indistinct yellow transverse stripes and spiral striæ; whorls 5, marked with very numerous convex spiral ridges and three stronger raised sharp keels; aperture dilated, nearly circular; peristome dilated, white, with sharp margins, left margin produced, not altogether covering the perforated axis. Breadth 11 lin.

*Helix tricarinata* Müller. *Hist. Verm.* ii. p. 84, n. 282; Chemn. *Conch. Cab.* ix. P. II, p. 85, t. 126, f. 1103, 1104; Gmel. *Syst.* p. 3621, n. 34.

*Hab.* Madagascar

(1386) *Cyclostomus euchilus*.

Shell turbinate globular, rather solid, crowdedly and obliquely striate, indistinctly decussated by more distant impressed lines, somewhat shining whitish, marbled with violaceous brownish and

## MOLLUSCA.

fulvous; spire turbinate raised, with the apex rather pointed; whorls 5½, convex, enlarging rapidly, last rounded, slightly depressed along the suture, with a single white peripheral band, crowdedly and deeply spirally furrowed beneath; umbilicus middle sized, funnel-shaped; aperture scarcely oblique, rather angularly rounded, shining and purplish flesh-coloured within; peristome nearly continuous, white, with the margins dilated above and joined by a slightly emarginated callus, right and basal margins very broad, vaulted and reflexed, left margin narrow, scarcely reflexed. Height 28, greatest breadth 43, least br. 32 mill.

*Cyclostoma euchilum*, *Pfr. in Proc. Z. S.* 1851. *Ic.* n. 288, t. 39. f. 3, 4.

*Cyclostoma euchilus*, *Pfr. Consp.* n. 303, p. 72. *Pneum. Mon.* p. 208.

*Hab.* Madagascar.

(1387) *Cyclostomus multifasciatus*.

Shell turbinate-conical, with numerous bands, subumbilicate, transversely striate; umbilicus covered; spire rather raised, very pointed; whorls 7, rounded, last ventricose; aperture wide, roundish, banded within; lip reflexed externally, with the edge white; columellar callus, saffron-coloured. Height 30-35, breadth 30-35 mill.

*Cyclostoma multifasciata*, *Grateloup, in Act. Bord.* xi p. 436, t. 3, f. 3.

*Tropidophora multifasciatum*, *Gray, Cat. Cycl.* p. 41, n. 16.

*Cyclostomus multifasciatus*, *Pfr. Consp.* n. 304; *Pneum. Mon.* p. 209.

*Hab.* Madagascar (Duisabo).

(1388) *Cyclostomus zonatus*.

Shell subumbilicate, globose-pyramidal, rather thin, nearly smooth, slightly decussated under a lens by longitudinal and spiral striæ, whitish-gray; spire conical, rather pointed; suture rather deep; whorls 6, rounded, last ventricose, girdled with a broad blackish band below the middle, spirally grooved round the umbilicus; aperture rather perpendicular, ovate-roundish; peristome interrupted, milk white, broadly reflexed. Height and breadth 28 mill.

*Cyclostoma zonatum*, *Petit, in Journ. Conch.* 1850, i. p. 50, t. 4. f. 7. *Cyclostomus zonatus*, *Pfr. Consp.* n. 305; *Pneum. Mon.* p. 209.

Smaller, with one or more bands; right margin of the peristome broadly expanded; columellar margin narrow, reflexed above into a short lamina, which almost covers the umbilicus. Height 20, greatest breadth 20, least br. 15 mill. (*Pfr. Ic.* n. 291, t. 39, f. 22, 23.)

*Hab.* Madagascar.

(1389) *Cyclostomus obsoletus*.

Shell turbinate, rather solid, faintly spirally striate above, slightly shining, ash-gray, painted with various blueish-fuscous bands; spire conical, rather pointed; whorls 6, convex, the last one deeply grooved spirally round the funnel-

shaped umbilicus; aperture scarcely oblique, ovate, grayish-chestnut-coloured within; peristome simple, white, broadly expanded, with the margins joined by a lunarly-indented callus. Height 22, greatest breadth 29, least br. 23 mill.

*Cyclostoma obsoleta*, Lam. Hist. vi. p. 144, n. 7; Ed. Desh. vii. p. 355; Deless. Recueil, t. 29, f. 11; Chenu, Ill. Conch. t. 1, f. 11. *Cyclostoma obsoletum*, Reeve, Conch. Syst. t. 183, f. 4; Sow. Thes. n. 88, p. 121, t. 27, f. 124; Pfr. Ic. n. 23, p. 32, t. 5, f. 8, 9.

*Cyclostomus insularis*, *Pfr. Consp.* n. 314, p. 63; *Pneum. Mon.* p. 215.

*Hab.* Isle of France.

## (1396) *Cyclostomus reticulatus*.

Shell turbinate, rather thin, marked with indistinct raised spiral lines, diaphanous, chestnut-coloured, reticulated irregularly with opaque white stripes and speckles; spire turbinate, rather pointed; whorls 5, very convex, enlarging rapidly, last rounded obsoletely grooved spirally within the middle sized umbilicus; aperture little oblique, roundish, slightly angulated; peristome rather simple, chestnut-coloured, with the edge white shortly interrupted, with the margins joined by thin callus. Height 13, greatest breadth 16, least br. 13 mill.

*Cyclostoma reticulatum*, *A. Adams & Reeve Voy. Samarang Moll.* p. 57, t. 14, f. 8; *Pfr. Id.* n. 237, t. 34, f. 13—16.

*Cyclostomus reticulatus*, *Pfr. Consp.* n. 315; *Pneum. Mon.* p. 216.

Larger; with the spiral striæ very obsolete; peristome broader, expanded, slightly reflexed; umbilicus wider; height 15, greatest breadth 22, least br. 17 mill.

*Hab.* Madagascar.

## (1397) *Cyclostomus Goudotianus*.

Shell globose-conical, thin, smooth, very faintly spirally striate, diaphanous, yellowish-fulvous, with 1—3 chestnut-coloured bands; spire conoidal, rather blunt; whorls 5, convex, last ventricose, sharply spirally furrowed beneath and within the middle-sized umbilicus; aperture rather circular, of the same colour within; peristome thin, expanded, slightly interrupted, with the columellar margin somewhat reflexed. Height 14, greatest breadth 17, least br. 14 mill.

*Cyclostoma Goudotianum*, *Sow. Thes.* n. 110, p. 130, t. 29, f. 193; *Pfr. Id.* n. 106, p. 106, t. 13, f. 8—10.

*Cyclostoma ligatum*, var. *Krauss. Südafr. Moll.* p. 82.

*Cyclostomus Goudotianus*, *Gray. Cat. Cycl.*

# MOLLUSCA.

p. 43, n. 2; *Pfr. Consp.* n. 316; *Pneum. Mon.* p. 216.

*Hab.* Natal (Krauss); East India (Menke).

## (1398) *Cyclostomus virgatus*.

Shell scarcely subperforate, turreted conical, rather thin, smooth, yellowish or whitish, girdled with chestnut-coloured lines and with a single broader band below the periphery; spire turreted, with the apex rather blunt; whorls 6, convex, last cylindrical, not descending; aperture scarcely oblique, ovate-roundish, uniformly coloured within; peristome sharp, slightly expanded, interrupted, with the columellar margin somewhat dilated, reflexed. Length 19, breadth 11 mill.

*Cyclostoma virgatum*, *Sow. Thes.* n. 111, p. 130, t. 29, f. 192, *Pfr. Id.* n. 105, p. 106 t. 13, f. 1—4.

*Cyclostomus virgatus*, *Gray. Cat. Cycl.* p. 44, n. 7; *Pfr. Consp.* n. 317; *Pneum. Mon.* p. 217.

With the spire less elongated, orange-coloured, with one chestnut-coloured band below the periphery, one sutural and two basal lines. (*Pfr. Id.* t. 13, f. 5 7.)

*Cyclostoma consocium*, *Feruss. Mus.*

*Cyclostoma consocius*, *Gray. Cat. Cycl.* p. 43, n. 3.

*Hab.* Madagascar.

## (1399) *Cyclostomus cincinnus*.

Shell conical, thin, slightly sculptured with crowded spiral ridges, uniformly white or marked with a single fuscous line below the periphery; spire conical, with the apex rather blunt; whorls 5, convex, the last one nearly smooth in the middle, crowdedly grooved beneath round the narrow scarcely pervious umbilicus; aperture nearly perpendicular, rather circular; peristome simple, sharp, with the margins almost contiguous; columellar margin slightly reflexed. Length 11, breadth  $7\frac{1}{2}$  mill.

*Cyclostoma cincinnus*, *Sow. in Proc. Z. S.* 1843, p. 60; *Thes.* n. 32, p. 102, t. 24, f. 77, 78; *Pfr. Id.* n. 140, p. 134, t. 18, f. 1-3.

*Cyclostoma modestum*, *Feruss. MSS. in Mus. Brit.*

*Cyclostomus cincinnus*, *Gray. Cat. Cycl.* p. 44, n. 8; *Pfr. Consp.* n. 320; *Pneum. Mon.* p. 218.

*Hab.* Madagascar? (Gray.)

## (1400) *Cyclostomus ligatulus*.

Shell oblong-conoidal, thin, umbilicated, subturreted, transversely slightly striate, many-banded; spire pointed; whorls 5-6, convex; aperture obovate, lip sharp, scarcely reflexed. Height 14-15, breadth 10 mill.

*Cyclostoma ligatula*, *Grateloup, in Act. Bord.* xi, p. 445, t. 3, f. 20.

*Cyclostomus ? ligatulus*, *Pfr. Consp.* n. 321 *Pneum. Mon.* p. 219.

*Hab.* Madagascar. (Mr. Duisabo).

## MOLLUSCA.

This may perhaps be identical with the preceding species.

### (1401) *Cyclostomus Zanguebaricus*.

Shell globose-conical, rather thin, sculptured with somewhat distant blunt spiral lines, whitish or yellowish; spire turbinate, rather pointed; whorls 5, convex, last ventricose, girdled with several chestnut-coloured lines and a single broader band below the middle, spirally grooved beneath round the narrow umbilicus; aperture nearly perpendicular, roundish, slightly angulated; peristome simple, scarcely interrupted on the penult whorl, very shortly expanded. Height  $8\frac{1}{2}$ , greatest breadth 10, least br. 9 mill.

*Cyclostoma Zanguebaricum*, *Petit*, in *Journ. Conch.* 1850, i. p. 53, t. 3, f. 5; *Pfr. Ic.* n. 292 t. 39, f. 24, 25.

*Cyclostomus Zanguebaricus*, *Pfr. Consp.* 322; *Pneum. Mon.* p. 219.

*Hab.* Zanzibar (Guillain).

### (1402) *Cyclostomus? filocinctus*.

Shell turbinate-globose, smooth near the depressed suture, otherwise girdled with numerous raised lines, whitish, with a fuscus periostraca; spire raised, rather conic, with the apex nipple-shaped; whorls  $4\frac{1}{2}$ , rounded, last cylindrical; aperture circular, scarcely angular above, equalling two-fifths of the total height, slightly sinuate near the umbilicus, which is deep and open; peristome double, inner edge simple, sharp, outer edge shortly reflected. Height  $2\frac{1}{2}$ , greatest breadth 3, least br.  $2\frac{1}{2}$  mill.

*Cyclostoma filocinctum*, *Benson*, in *Ann. and Mag. N. H.* 1851, viii. p. 188. *Pfr. v. Ic.* n. 409, t. 49, 26-28

*Cyclostomus? filocinctus*, *Pfr. Consp.* n. 325; *Pneum. Mon.* p. 221.

*Hab.* The Neilgherries Mountains (Jerdon).

### (1403) *Cyclostomus undulatus*.

Shell perforated, globose-conic, solid, spirally grooved all over; the furrows being deeper near the suture and on the lower side, fulvous flesh-coloured, with a single chestnut-coloured band below the periphery; spire conic, rather pointed; whorls 5, convex, increasing rapidly, undulated on the upper edge near the suture, which is well marked; aperture oblique, nearly circular, brownish within and banded with white and chestnut-colour; peristome simple, straight, with the margins joined angularly; right margin somewhat sinuate; columellar margin slightly thickened and dilated. Height 12, greatest breadth 13, least br. 15 mill.

*Cyclostoma fimbriata*, *Lam. Hist.* vi. p. 148, n. 24; *Ed. Desh.* viii. p. 360, n. 23.

(Not *Schum.*, nor *Quoy*, nor *Deless.*)

*Cyclostoma undulatum*, *Sow. Thes.* 25, p. 99, t. 23, f. 29, 30; *Pfr. Ic.* n. 94, p. 97, t. 12, f. 24-26.

*Cyclostoma fimbriatum*, *Petit*, in *Journ. Conch.* 1850, i. p. 42.

## MOLLUSCA.

*Cyclostomus undulatus*, *Gray*, *Cat. Cycl.* p. 44, n. 6; *Pfr. Pneum. Mon.* p. 223.

*Cyclostomus fimbriatus*, *Pfr. Consp.* n. 328.

*Hab.* The island of Mauritius.

### (1404) *Cyclostomus? gratus*.

Shell perforate, oblong-conic, solid, minutely crossed by raised spiral and very crowded longitudinal striæ, somewhat shining, flesh-coloured; spire stair-like, conic, with the apex purplish, rather blunt; whorls 5, convex, the last one slightly flattened beneath, somewhat angular at its periphery and round the perforation; aperture oblique, nearly circular, angular above, fire red within; peristome simple, continuous, straight, with the left margin shortly expanded above, slightly reflected at its lower part. Operculum? Length 7, breadth 5 mill.

*Cyclostoma gratum*, *Petit*, in *Journ. Conch.* 1850, i. p. 53, t. 3, f. 10; *Pfr. Ic.* n. 236, t. 34, f. 11, 12.

*Cyclostoma tricolor*, *Pfr. in Z. f. M.* 1849, p. 123, (March, 1850).

*Cyclostomus? gratus*, *Pfr. Consp.* n. 339; *Pneum. Mon.* p. 231.

*Hab.* The island of Abd-el-Goury, near Socotora.

### (1405) *Lithidion sulcatum*.

Shell convex-depressed, solid, girdled with rather sharp raised spiral ridges, slightly shining, blueish-white; spire somewhat raised, with the apex blueish, mucronulate; whorls 5, moderately convex, last rounded, deflected anteriorly; umbilicus wide, smooth internally; aperture very oblique, rather circular, brown inside; peristome rather thickened, slightly expanded, with the margins approximate, right margin sinuate. Height 5, greatest breadth 10, least br. 9 mill.

*Cyclostoma lithidion*, *Sow. Thes.* n. 61, p. 111, t. 31, f. 262; *Pfr. Ic.* n. 160, p. 150, t. 20 f. 20-22

*Lithidion sulcatum*, *Gray*, *Cat. Cycl.* p. 35, n. 1; *Pfr. Consp.* n. 255; *Pneum. Mon.* p. 176.

*Hab.* Yemen, Arabia (Powis, Sowerby).

### (1406) *Lithidion desciscens*.

Shell widely umbilicate, depressed semiglobose, slightly and closely spirally furrowed above, whitish; spire convex; whorls  $4\frac{1}{2}$ , moderately convex, the last one cylindrical, suddenly deflexed anteriorly, smooth beneath; aperture nearly horizontal roundish, sublunate white inside; peristome thickened, with the margins distant joined by callus, basal margin reflexed, columellar margin suddenly ascending in a curve. Height  $5\frac{1}{2}$ , greatest breadth 10, least br.  $8\frac{1}{2}$  mill.

*Cyclostoma desciscens*, *Pfr. in Proc. Z. S.* 1851; *Ic.* n. 250, t. 35, f. 25, 26.

*Lithidion desciscens*, *Pfr. Consp.* n. 256, p. 60, *Pneum. Mon.* p. 177.

*Hab.* Socotora.

### (1407) *Lithidion Souleyetianum*.

Shell convex-conoidal, solid, sculptured above

with six raised spiral ridges and with crowded transverse striae, shining, brownish-flesh-coloured; spire conoidal, with the apex rather blunt; whorls 5, last cylindrical, deflexed anteriorly, smooth beneath; umbilicus wide, open; aperture very oblique, saffron-coloured inside, irregularly rounded; peristome white, slightly thickened, interrupted, with the margins distant, upper margin rather expanded, basal margin shortly reflexed. Height  $4\frac{1}{2}$ , greatest breadth 8, least br. 7 mill.

*Cyclostoma Souleyetianum*, *Petit, in Journ. Conch.* 1850, i. p. 52, t. 3, f. 6; *Pfr. Ic.* n. 249. t. 35, f. 23, 24.

*Cyclostoma paradoxum*, *Pfr. in Z. f. M.* 1849, p. 128.

*Lithidion Souleyetianum*, *Pfr. Consp.* n. 257; *Pneum. Mon.* p. 177.

*Hab.* The Island of Abd-el-Goury, near Socotora (Guillain).

(1408) *Lithidion niveum*.

Shell broadly umbilicate, rather depressed, solid, indistinctly spirally striate above, slightly shining, white; spire little raised, mucronate; suture deep; whorls  $4\frac{1}{2}$ , moderately convex, the last one keeled above the middle, convex and smooth beneath; aperture diagonal, rather circular, flesh-coloured inside; peristome rather simple, shortly interrupted, with the margins joined by thin callus, upper margins sinuate, slightly expanded. Height 5, greatest breadth 11, least br. 9 mill.

*Cyclostoma niveum*, *Petit, in Journ. Conch.* 1850, i. p. 52, t. 3, f. 7; *Pfr. Ic.* n. 249. t. 35, f. 20-22.

*Lithidion niveum*, *Pfr. Consp.* n. 259, *Pneum. Mon.* p. 178.

*Hab.* Madagascar.

*Sub-genera.* *Otopoma* (foliaceum). *rec.* 15 sp.  
*Otopoma.* *Gray.*

28\*. *O. blennus*, B.—Moulmein. Rare.

(1409) *Otopoma clausum*.

Shell orbiculate-convex, rather solid, slightly and crowdedly spirally furrowed above, smooth beneath, flesh-coloured-whitish; spire short, blunt; suture flat, chestnut-coloured in the upper whorls; whorls 4, scarcely convex, the last one descending anteriorly, rather flattened beneath; aperture oblique, roundish-ovate, rather angular above, yellowish inside; peristome simple, straight, with distant margins, right margin sinuate, columellar margin dilated into a glassy, broad, reflexed lamina, which is affixed on all sides, and covers perfectly the umbilicus. Height 8, greatest breadth  $14\frac{1}{2}$ , least br.  $11\frac{2}{3}$  mill.

*Cyclostoma clausum*, *Sow. Thes.* n. 104, p. 128, t. 31, f. 266, 267; *Pfr. Ic.* n. 157, p. 147, t. 20, f. 13-15.

*Otopoma clausum*, *Gray. Cat. Cycl.* p. p. 36, n. 2; *Pfr. Consp.* n. 260; *Pneum. Mon.* p. 179.

Smaller, spire more raised, periphery marked with a single reddish-brown line; height  $7\frac{1}{2}$ ,

greatest breadth  $12\frac{1}{2}$ , least br. 10 mill. (*Pfr. Ic.* t. 42, f. 13-15).

*Hab.* Yemen, Arabia (Powis).

(1410) *Otopoma albicans*.

Shell depressed-globose, smooth, indistinctly marked with spiral and oblique striae, rather shining, white; spire broadly conoidal, blunt; whorls 5, convex, the upper ones distinctly furrowed concentrically, the last one descending anteriorly, rather ventricose; aperture slightly oblique, ovate; peristome continuous, shortly affixed, thickened and expanded, right margin arcuately dilated; columellar margin angularly produced near the umbilicus, which is wide and somewhat funnel-shaped. Height 23, greatest breadth 35, least br. 29 mill.

*Cyclostoma albicans*, *Sow. Spec. Conch.* ii. *Cycl.* f. 104, 105; *Sow. in Zool. of Beech. Voy.* p. 146, t. 38, f. 30, *Sow. Thes.* n. 79, p. 118, t. 26, f. 110-112; *Pfr. Ic.* n. 83, p. 87, t. 11, f. 3, 14.

*Otopoma albicans*, *Gray. Cat. Cycl.* p. 36, n. 5; *Pfr. Consp.* n. 262; *Pneum. Mon.* p. 181.

*Hab.* The Island of Hainan, South China (Benson).

(1411) *Otopoma naticoides*.

Shell conoidally-globose, solid thick rose-coloured-whitish; spire conoidal, rather blunt; whorls  $5\frac{1}{2}$ , convex, the upper ones minutely decussated, the last one closely wrinkled longitudinally, crossed by obsolete spiral folds; aperture little oblique, ovate, yelk-coloured inside; peristome thickened, slightly reflected, with the margins angularly joined by a thick, whitish deposit; columellar margin dilated into a rather thick, vaulted lamina, which in full-grown shells nearly covers the umbilicus. Height 35, greatest breadth 41, least br. 34 mill.

*Turbo foliaceus*, *Chemn. Conch. Cab.* x. p. ii, p. 59, t. 123, f. 1069, 1070? *Gmel. Syst.* p. 3602, n. 104?

*Cyclostoma naticoides*, *Recluz in Rev. Zool.* 1843, p. 3; *Mag. Zool.* 1843, t. 73, *Pfr. Ic.* n. 28, p. 37, t. 6, f. 14.

*Hab.* Socotora.

(1412) *Otopoma unifasciatum*.

Shell subglobose, with an acuminate but decollated spire, consisting of four rounded, smooth volutions, with faint spiral striae; volutions whitish, the last with a single fuscous band near the base; suture distinct; aperture circular, orange-coloured within; peristome white, reflected, sinuated above, thickened on the side of the umbilicus, which is small and spirally grooved, Height 20, breadth 22 mill.

*Cyclostoma unifasciatum*, *Sow. in Cat. Tank. App.* p. viii. n. 1016; *Thes.* n. 81, p. 119, t. 26, f. 105, 106; *Pfr. Ic.* n. 188, p. 173, t. 25, f. 4, 5 (from *Sow.*).

*Otopoma unifasciatum*, *Pfr. Consp.* n. 265; *Pneum. Mon.* p. 183.

# MOLLUSCA.

*Hab.* Madagascar (Sowerby).  
Compare *Otopoma Listeri*.

## (1413) *Otopoma? Philippianum*.

Shell globose-turbinate, thin, faintly striate, decussated above by minute spiral lines, fulvous-whitish, painted, on the upper side, with 3—4 narrow reddish-brown bands; spire turbinate, with the apex blackish; whorls 5—5½, rounded, the last one girdled, below the middle, with a single broader band smooth and uniformly white beneath; aperture little oblique, rather angularly roundish, of the same colour within; peristome slightly interrupted, with the margins joined by thin callus, right margin straight, columellar margin dilated, freely reflected, half concealing the narrow pervious umbilicus. Operculum? Height 22, greatest breadth 26, least br. 21 mill.

*Turbo ligatus* var., *Chemn. Conch.* ix. P. ii. p. 60, t. 123, f. 1073; 1074, (ed. alt. t. 4, f. 14. 15.)

*Cyclostoma ligatum*, *Sow. Thes.* n. 21, p. 98, t. 23, f. 24. (Not Muller.)

*Cyclostoma Philippianum*, *Pfr. Ic.* n. 356, t. 44, f. 23, 24.

*Otopoma Philippianum*, *Pfr. Consp.* n. 266, p. 61; *Pneum. Mon.* p. 183.

Locality unknown.

## (1414) *Otopoma? clathratulum*.

Shell conoidally-globose, rather thick, regularly trellised above by crowded longitudinal and spiral raised lines, brownish-flesh-coloured, marked often with small brown spiral lines above; spire conoidal, rather blunt; whorls 5, convex, the upper ones blackish-bordered above the suture, the last one smooth below the middle; umbilicus narrow, pervious; aperture obliquely ovate, angulated above, yelk-coloured within; peristome straight, rather thickened, with the margins nearly contiguous, angularly joined by a continued callus; columellar margin scarcely reflexed. Height 13, greatest breadth 22, least br. 18 mill.

*Cyclostoma clathratula*, *Riccluz. in Rev. Zool.* 1843, t. 74.

*Cyclostoma Clathratulum*, *Sow. in Proc. Z. S.* 1843, p. 30; *Thes.* n. 17, p. 97, t. 23, f. 15, 16; *Pfr. Ic.* n. 29, p. 38, t. 5, f. 5-7.

*Otopoma foliaceum* jun., *Gray. Cat. Cycl.* p. 35.

*Otopoma clathratulum* *Pfr. Consp.* n. 267; *Pneum. Mon.* p. 184.

*Hab.* Yemen, Arabia (Sowerby), Socotora (*Riccluz*).

## (1415) *Otopoma? vitellinum*.

Shell globose-conical, solid, coarsely decussated by crowded striæ of growth and more crowded spiral ridges, yellowish-reddish, with irregular paler stripes; spire raised, conical, with the apex rather blunt, blackish; whorls 5, convex, the last rounded, smooth below the middle, spirally

# MOLLUSCA.

grooved in the narrow pervious umbilicus; aperture scarcely oblique, ovate-roundish; peristome simple, with the margins approximate, joined by callus; right margin straight, rather sinuate; left margin dilated and expanded in the middle. Height 17, greatest breadth 19, least br. 17 mill.

*Cyclostoma vitellinum*, *Pfr. in Proc. Z. S.* 1851; *Ic.* n. 353, t. 43, f. 35, 36.

*Otopoma? vitellinum*, *Pfr. Consp.* n. 268, p. 61; *Pneum. Mon.* p. 184.

*Hab.* Madagascar.

## (1416) *Otopoma Listeri*.

Shell globose-conical, thick, smooth, shining-flesh-coloured; spire conical, with the spire rather pointed, horn-coloured; whorls 5, convex, the last one angulated indistinctly, sometimes girdled with a single reddish-brown line below the middle, deeply spirally grooved beneath; aperture somewhat oblique, rather ovate, fulvous within; peristome simple, straight, with distant margins angularly joined by thin callus, columellar margin dilated and reflexed, sometimes altogether closing the very narrow umbilicus. Height 13, greatest breadth 15½, least br. 13½ mill.

*Hab.* The island of Mauritius.

## (1417) *Otopoma? spurcum*.

Shell orbiculate-turbinate, obconical, dirty white, widely umbilicate, striate longitudinally; spire short, pointed; whorls convex; aperture open, rounded; labrum simple, sharp. Height 15, breadth 20 mill.

*Cyclostoma spurca*, *Grateloup, Act. Soc. Linn. Bord.* xi. p. 444, t. 3, f. 12.

*Optoma spurcum*, *Gray, Cat. Cycl.* p. 37, n. 9; *Pfr. Consp.* 272; *Pneum. Mon.* p. 187.

*Hab.* Bombay?

## (1418) *Otopoma multilineatum*.

Shell globose-conoidal, solid, wrinkled and striate longitudinally, shining, fulvous; spire conical, with the apex rather blunt; whorls 4½-5, convex, the last ventricose, marbled with white and fulvous, girdled with chestnut-coloured lines; aperture somewhat oblique, roundish, rather angular, of the same colour within; peristome slightly expanded, thickened, with the margins distant, right margin angularly sinuous, deeply indented, columellar margin vaulted and reflected, almost closing the perforated axis. Height 14, greatest breadth 17, least br. 13½ mill.

*Hab.* The Island Opara (H. Cuming).

(1424) *Realia multilirata*.

Shell perforate, ovate-conic, rather solid, sculptured with rather sharp and close set spiral ridges (one on the middle and another on the base being stronger) reddish-flesh-coloured; spire conic, rather pointed; whorls  $5\frac{1}{4}$ , the upper ones rather flat, last more convex; aperture slightly oblique, angularly ovate; peristome simple, straight, with the margins approximate, columellar margin emarginated above, dilated and somewhat reflexed at its lower part. Length  $8\frac{1}{4}$ , breadth 5 mill.

*Cyclostoma multiliratum*, *Pfr. in Proc. Z. S.* 1851.

*Omphalotropis multilirata*, *Pfr. Consp. n.* 461. p. 70; *Pneum. Mon.* p. 311.

*Hab.* Isle of France (Sir David Barclay).

(1425) *Realia globosa*.

Shell umbilicated, globose conic, thin, very faintly striated, diaphanous, not shining, cinnamon coloured, painted with opaque whitish spots, which are somewhat arranged into bands; spire conic, with the apex very pointed; whorls 6, the upper ones scarcely convex, last globose, with a subtle thread-like basal keel; aperture slightly oblique, ovate; peristome simple, with the margins almost contiguous, right margin curved strongly, columellar margin dilated and spreading in the middle. Length 8, breadth 5 mill.

*Cyclostoma globosum*, *Bens. MSS.* (fide Barclay); *Pfr. Ic. n.* 295, t. 39. f. 14-16.

*Omphalotropis globosa*, *Pfr. in Proc. Z. S.* 1851. *Consp. n.* 462. p. 71; *Pneum. Mon.* p. 311.

*Hab.* Trees in woods on the island of Mauritius (Sir D. Barclay).

(1426) *Realia expansilabris*.

Shell scarcely perforate, ovate-conic, thin, rather smooth, slightly shining, pale yellow, minutely marbled with horn-colour and girdled with one or two reddish-brown bands below the periphery; spire elevated conic, rather pointed; whorls 6, scarcely convex, last with a thread-like keel in the middle and at the base; aperture oblique, ovate; peristome equally and narrowly expanded all round, white with the margins rather distant. Length  $5\frac{1}{2}$ , breadth 3 mill.

*Cyclostoma expansilabre*, *Pfr. in Proc. Z. S.* 1851; *Ic. n.* 296, t. 39, f. 17-19.

*Omphalotropis expansilabris*, *Pfr. Consp. n.* 464, p. 71; *Pneum. Mon.* p. 312.

*Hab.* The island of Mauritius (Sir D. Barclay).

*Cyclophorus*, *rec.* 90 sp.

(1427) *Cyclophorus Himalayanus*.

Shell globose turbinated, rather solid, with 10-12 blunt spiral ribs and obsolete interposed lines, whitish, with a deciduous periostraca of ... colour; spire turbinated, reddish-brown and rather pointed above; whorls 5, moderately convex, the

last one ventricose, scarcely compressed around the umbilicus, which is narrow and funnel shaped; aperture nearly perpendicular, circular; peristome simple, continuous, shortly affixed, brownish fiery, rather thickened, shortly expanded, somewhat angulated above. Operc? Height 35, greatest breadth 48, least br. 39 mill.

*Cyclostoma Himalayanum*, *Pfr. in Proc. Z. S.* 1851, p.; *Ic. n.* 228, t. 33. f. 10, 11.

*Cyclophorus Himalayanus*, *Pfr. Consp. n.* 65, p. 50; *Pneum. Mon.* p. 55.

*Hab.* India, the Himalayan Mountains.

(1428) *Cyclophorus Simensis*.

Shell turbinated depressed, solid, smooth, chestnut-coloured, elegantly painted with angular whitish stripes; spire shortly turbinated, with the apex rather blunt; whorls 5, convex, rather flattened near the deep suture, the last one rounded at the periphery, obsolete compressed around the funnel-shaped umbilicus; aperture little oblique, large, circular, whitish inside; peristome rather thickened and reflected, yellowish flesh coloured shortly affixed to the penult whorl. Operc? Height 29, greatest breadth 51, least br. 40 mill.

*Coclostoma Siamense*, *Sow. Thes. Suppl. n.* 178, p. 158, t. 31 A. f. 292, 293; *Pfr. Ic. n.* 331, t. 42, f. 5, 6.

*Cyclophorus Siamensis*, *Pfr. Consp. n.* 67; *Pneum. Mon.* p. 56.

*Hab.* Siam.

(1429) *Cyclophorus tuba*.

Shell suborbicular, rather depressed, thin, smooth, whitish, varied and clouded with reddish brown; spire short, rather flattened, acuminate at the apex; volutions 5, flattish, the posterior carinated, the last very large and rounded; aperture very large, circular, expanded, whitish, peristome whitish, thin, broad, revolute, interrupted over the last volution; umbilicus large, Operculum reddish-horn-coloured. Height 25, breadth 45 mill. (Sow.)

*Cyclostoma tuba*, *Sow. in Proc. Z. S.* 1843. p. 83. *Thes. n.* 91, p. 122 t. 27. f. 129, 130; *Pfr. Ic. n.* 183. p. 189. t. 23, f. 10, 11; *Sonleyet. in Voy. Bonite Moll t.* 30, f. 25-27.

A little smaller and more depressed, with the last whorl subcarinated at the periphery, and with the peristome not so broadly expanded scarcely reflected.

*Hab.* Malacca, Mount Ophir (H. Cuming.)

(1430) *Cyclophorus Pearsoni*.

Shell depressed-turbinated, smooth, with obsolete spiral striae, varied and broadly banded with chestnut-brown above, with brownish spiral lines beneath, with a white band at the periphery, and another of blackish-chestnut-colour immediately below it; spire depressed-conoidal with the apex

## MOLLUSCA.

pointed; whorls 5, moderately convex, the last one large, convex beneath; aperture scarcely oblique, large, circular blueish inside; peristome expanded, reflected on all sides, pale orange-coloured; the margin joined by a short callus; umbilicus rather narrow, open, more narrow interiorly. Height 25, greatest breadth 42, least br. 33 mill. (B.)

*Cyclostoma Pearsoni*, Benson, in *Ann. and Mag.* 28, ser. viii. 1851, p. 185; *Pfr. Ic.* n. 411, t. 49, f. 34-36.

*Cyclophorus Pearsoni*, *Pfr. Consp.* n. 70, *Pneum. Mon.* p. 58.

*Hab.* India, the Khasya Hills.

(1431) *Cyclophorus volvulus*.

Shell globose-conic, solid, smooth, fulvid, varied with chestnut-coloured stripes and spots; spire conoidal, with the apex blunt; whorls 5, rounded, the last one very obsolete angulated at the periphery, with a broad blackish-chestnut-coloured band below the periphery; umbilicus of middle size, funnel-shaped; aperture oblique, nearly perpendicular, blueish-whitish within; peristome whitish, double; internal edge continuous, thickened rather produced; external edge reflected emarginated near the penult whorl. Operculum, with a lamellar margin to the whorl. Height 23, greatest breadth 37, least br. 29 mill.

*Hab.* India, Tavoy and Mergui, British Burmah.

(1435) *Cyclophorus Bensoni*.

Shell globose-turbinate, solid, minutely decussated with oblique and crowded spiral lines, whitish-fulvous, marbled with chestnut; spire turbinate, rather blunt; whorls 5, convex, the upper ones uniformly dirty brownish, the following ones painted with flames, the last one large, obsoletely keeled, bearing on the keel a blackish band, and on both sides unequal chestnut-coloured bands, pale and rather compressed round the umbilicus, which is narrow and funnel-shaped; aperture rather oblique, nearly circular, milk-white inside; peristome continuous, fiery orange red, shortly affixed, shortly and convexly reflected. Operc. ? Height 26, greatest breadth 43, least br. 34 mill.

*Cyclostoma Bensoni*, Pfr. in *Proc. Z. S.* 1851, *Ik.* n. 225, t. 32, f. 11-13.

*Cyclophorus Bensoni*, Pfr. *Consp.* n. 79, p. 52; *Pneum. Mon.* p. 63.

Locality unknown.

(1436) *Cyclophorus Borneensis*.

Shell depressed-turbinate, rather thin, striate sculptured with very fine and crowded spiral lines, fulvous above, with chestnut-coloured stripes and spots; spire conoidal, with the apex rather pointed; suture flat, bordered; whorls 5, scarcely convex, the last one sharply keeled, marked with a broad chestnut-coloured band, which is spotted with white below the keel, rather compressed round the middle-sized umbilicus; aperture oblique, rather truncated-oval; peristome shortly expanded, not thickened, with the margins somewhat distant, united by a thin deposit. Operculum reddish, concave externally. Height 20, greatest breadth 40, least br. 33 mill.

*Cyclostoma Borneense*, Metcalfe, in *Proc. Z. S.* 1851; Pfr. *Ik.* n. 384, t. 47, f. 1-3.

*Hab.* India, Tenasserim, and Java?

(1438) *Cyclophorus Zollingeri*.

Shell umbilicate, orbiculate-conic, transversely substriate, brownish, with white points and spots; spire prominent, with the nucleus transversely strongly striate; suture linear; whorls  $4\frac{1}{2}$ -5, rather flat, marked above with small oblique ribs, which are crossed rectangularly by the striae of growth; last whorl furnished with an obtuse keel, which is articulated with white and brownish, rather flattened beneath, with the back band obtuse; aperture broadly orbicular, violaceous, with the margin rather thickened, expanded. Operc. obscurely spiral, smooth inside, with the centre prominent, Height 17-21, greatest breadth 23-31, least br. 21-25 mill. (M.)

*Cyclophorusma Zollingeri*, *Monsf. Jav. Moll.* p. 55, t. 7, f. 2.

*Cyclostoma Zollingeri*, Pfr. *Consp.* n. 82; *Pneum. Mon.* p. 64.

*Hab.* Java.

(1439) *Cyclophorus porphyriticus*.

Shell depressed conoidal thin, sculptured with very crowded, distinct, raised, somewhat undulate spiral lines, whitish, marked above with dark chestnut, more pale beneath, sprinkled with angular spots, which are larger along the suture, and with two dark bands, which are articulated with white, the one of which at the periphery, the other below; spire short with the apex pointed; suture scarcely distinct; whorls  $4\frac{1}{2}$ , rather flattened, the last one angulate, nearly flat beneath; umbilicus middle-sized; aperture large ovate circular, grayish-white; peristome thin, expanded, and reflected, with the margins convergent, united by a thin deposit, columellar margin narrower, slightly emarginate. Operc. ? Height 18, greatest breadth 31, least br.  $24\frac{1}{2}$  mill (B.)

*Cyclostoma porphyriticum*, Benson in *Ann. and Mag.* 2nd ser. viii. 1851, p. 187; Pfr. *Ik.* n. 415, t. 50, f. 22-24.

*Cyclophorus porphyriticus*, Pfr. *Consp.* n. 83; *Pneum. Mon.* p. 65.

*Hab.* East India.

(1440) *Cyclophorus expansus*.

Shell turbate, rather globular, solid, with crowded spiral striæ, opaque, marbled above with chestnut and whitish; spire conoidal, with the apex rather pointed; whorls 5, moderately convex, the last one more convex, dilated, slightly keeled at its periphery; painted beneath with narrow chestnut-coloured bands; umbilicus narrow, open; aperture nearly perpendicular, rather circular; peristome rather simple, continuous, shortly affixed, pale orange-coloured, flatly expanded all round into the plane of the aperture, with the edge slightly reflected. Operc.? Height 19, greatest breadth 30, least br. 22 mill.

*Cyclostoma expansum*, *Pfr. in Proc. Z. S.* 1851;  *Ic. n.* 290, t. 39, f. 20, 21.

*Cyclophorus expansus*, *Pfr. Consp. n.* 84, p. 52; *Pneum. Mon.* p. 65.

*Hab.* Tavoy, Burmah.

(1441) *Cyclophorus Cantori*.

Shell subglobose-conoidal, with very numerous, slight, spiral, striæ, fulvid, with a grayish-white periostraca, which is marbled, spotted, and lineated with reddish-brown and girdled usually with one peripheral blackish band; spire conoidal, pointed; whorls 5, moderately convex, the upper ones obliquely striate, the last whorl obsoletely angulate; umbilicus rather narrow, open; aperture nearly perpendicular, large, circular, with the margins united by a thin deposit; peristome expanded, rather flattened and reflected. Operc. typical. Height  $14\frac{1}{2}$ -19, greatest breadth 24-30, least br. 19-23 mill. (*B.*)

*Cyclostoma Cantori*, *Benson, in Ann. and Mag.* 2nd. ser. viii. 1851, p. 186; *Pfr. Ic. n.* 414, t. 50 f. 4-6.

*Cyclophorus Cantori*, *Pfr. Consp. n.* 85; *Pneum. Mon.* p. 65.

*Hab.* The Island of Penang (Cantor).

(1442) *Cyclophorus Menkeanus*.

Shell turbate, solid, marbled with chestnut and white, with crowded spiral lines above, which are slightly decussated by the striæ of growth; spire short, conoidal, blunt; whorls 5, convex, the last one angulated at its periphery, with a peripheral white band, and another, which is broader and blackish-chestnut-coloured, immediately below it, more smooth beneath, white round the middle-sized umbilicus; aperture oblique, nearly circular, pale orange-coloured inside; peristome double; inner edge continuous, wrinkled, very much protracted at the upper and right side; external edge thickened, expanded, angulated above, interrupted near the penult whorl. Operc.? Height 20, greatest breadth 30, least br. 28 mill.

*Cyclostoma Menkeanum*, *Philippi, in Z. f. M.* 1847, p. 123; *Pfr. Ic. n.* 185, p. 171, t. 28, f. 6-8.

*Cyclophorus Menkeanus*, *Pfr. in Z. f. M.* 1847, p. 107; *Consp. n.* 86; *Gray. Cat. Cycl.* p. 18, n. 10; *Pfr. Pneum. Mon.* p. 66.

*Hab.* Ceylon, Point de Galle (Benson).

(1443) *Cyclophorus amœnus*.

Shell depressed-turbinate, solid, smooth, white, very elegantly painted with numerous chestnut-coloured fulvous lines, which are interrupted by arrow-shaped spots; spire conoidal, blunt; whorls  $4\frac{1}{2}$ , moderately convex, the last one inflated above, with a rather compressed keel at its periphery, below which is placed a darker band, convex beneath, white round the narrow funnel-shaped umbilicus; aperture little oblique, nearly circular; peristome double; inner edge continuous, straightly produced; outer edge thick, expanded, scarcely indented on the penult whorl. Operc.? Height 18, greatest breadth 30, least br. 24 mill.

*Cyclostoma amœnum*, *Pfr. in Proc. Z. S.* 1851;  *Ic. n.* 362, t. 45, f. 11, 12.

*Cyclophorus amœus*, *Pfr. Consp. n.* 87, p. 52; *Pneum. Mon.* p. 66.

Locality unknown.

(1444) *Cyclophorus turgidus*.

Shell turbate-globose, solid, striate, and minutely foveate, fulvous, with chestnut-coloured bands and interrupted lines, and usually with arrow-shaped spots along the suture; spire turbate, with the apex rather blunt; whorls 5, convex, the last one inflated above, surrounded below the middle, with a cord-like keel and with a broader blackish band, rather flattened beneath, somewhat compressed round the umbilicus, which is narrow, funnel-shaped; aperture oblique, rounded, scarcely angular; peristome double; inner edge continuous; outer edge thickened, expanded, shortly interrupted near the penult whorl. Operc. pale horn-coloured. Height 16-18, greatest breadth 22-27, least br.  $18\frac{1}{2}$ -23 mill.

*Cyclostoma crassum*, *Pfr. in Proc. Z. S.* 1851, *Jul. Not Adams*.

*Cyclostoma turgidum*, *Pfr. Ic. n.* 241, t. 35, f. 15, 16.

*Cyclophorus turgidus*, *Pfr. Consp. n.* 88, p. 53; *Pneum. Mon.* p. 67.

*Hab.* Liew Kiew and Ibyat, Bashee group.

(1445) *Cyclophorus punctatus*.

Shell depressed-turbinate, rather thin and smooth (with very minute oblique striæ), pale yellowish-horn-coloured, painted with chestnut-coloured points and arrow-shaped spots, which are arranged in single rows; spire short, with the apex rather pointed, blackish; whorls 5, convex, the upper ones often with waving streaks, the last one ventricose, rather angulate at its periphery and marked with a dark chestnut-coloured band, which is denticulated on both sides; umbilicus narrow, open; aperture rather oblique, nearly circular, whitish inside; peristome shortly

## MOLLUSCA.

expanded all round, with the margins united by a thin deposit. Operc? Height 18, greatest breadth 25, least br. 20 mill.

*Cyclostoma punctata*, Grateloup, *Act. Soc. Bord.* xi. p. 440, t. 3, f. 10.

*Cyclostoma punctatum* *Pfr. Ic.* n. 31, p. 40, t. 5, f. 12, 13.

*Cyclostoma irroratum*, Sow. in *Proc. Z. S.* 1843, p. 61; *Thes.* n. 94, p. 123, t. 27, f. 134, 135.

*Cyclophorus punctatus*, *Pfr. in Z. f. M.* 1847, p. 107, n. 11; *Consp.* n. 89; *Gray, Cat. Cycl.* p. 18, n. 11; *Pfr. Pneum. Mon.* p. 67.

*Hab.* Ceylon (Grateloup), China (Sowerby).

Shell marked all over with chestnut-coloured flames and stripes; height 16, greatest breadth 24, least br. 19 mill.

*Hab.* Philippine Island, Basilan (H. Cuming).

(1446) *Cyclophorus eximius*.

Shell turbate-depressed, solid, keeled, whitish, with brown angular stripes, covered with a chestnut-coloured fulvous periostraca; spire shortly turbate, with the apex rather pointed; whorls 5, moderately convex, furnished above with three obtuse spiral ribs, minutely decussated by spiral and oblique striæ; last whorl very large, blackish-chestnut-coloured and ventricose below the keel, which is rather sharp, somewhat compressed round the umbilicus, which is rather broad and funnel-shaped; aperture little oblique, nearly circular; peristome pale flesh-coloured yellowish, double; inner edge continuous, expanded, affixed to the outer edge, which is rather interrupted, expanded into the plane of the aperture, with the columellar margin dilated, somewhat reflected. Operc.? Height 32, greatest breadth 62, least br. 47 mill.

*Cyclostoma eximium*, Mousson, *Jav. Moll.* p. 53, t. 7, f. 1; *Pfr. Ic.* n. 227, t. 33, f. 1, 2.

*Cyclophorus eximius*, *Pfr. Consp.* n. 92; *Pneum. Mon.* p. 69.

*Hab.* India, Khasya Hills (Mus. Cuming); Java? (Mousson.)

(1447) *Cyclophorus Ceylanicus*.

Shell depressed-turbinate, solid, decussated by very numerous sharp raised ridges, between which are placed smaller ones, and very crowded longitudinal striæ, dark chestnut-coloured, painted with narrow waving white streaks, spiral conoidal, with the apex rather blunt; whorls 5, convex, increasing rapidly, the last one marked with a broad blackish band below the chief carina, which is situated nearly on the middle, and is sharper than the others, rather compressed, and straw-yellow round the funnel-shaped umbilicus; aperture rather oblique, nearly circular, blueish white inside; peristome thickened, white, with the margins united above by a thin deposit into a channelled angle, right margin expanded columellar margin reflected. Operc. thin, rather

## MOLLUSCA.

concave externally. Height 24, greatest breadth 37, least br. 30 mill.

*Cyclostoma Ceylanicum*, Sow. *MSS.*; *Pfr. Ic.* p. 171, n. 186, t. 29, f. 1-3.

*Cyclostoma Indicum*, Sow. *Thes. Suppl.* n. 190, p. 163, t. 31, B f. 320, 321.

*Cyclophorus Ceylanicus*. *Pfr. Consp.* n. 93; *Pneum. Mon.* p. 70.

*Hab.* Ceylon.

(1448) *Cyclophorus stenomphalus*.

Shell somewhat top-shaped, solid, sculptured above with numerous strong spiral ridges, between which are situated smaller ones, fulvous, with more or less distinct dark marble painting, and an articulated band along the suture; spire turbate, with the apex pointed; whorls  $5\frac{1}{2}$ , convex, the last one furnished with a stronger keel at the periphery, ventricose and spirally striate beneath; umbilicus very narrow, scarcely going through; aperture large, nearly circular; peristome double; inner edge pale orange-coloured; outer edge expanded, rather thickened, dilated and angulated above, with the columellar margin thickened, shortly reflected. Operc.? Height 24, greatest breadth 35, least br. 23 mill.

*Cyclostoma stenomphalus*, *Pfr. in Z. f. M.* 1846, p. 44; *Ic.* n. 54, p. 59, t. 8, f. 5, 6.

*Cyclophorus stenomphalus*, *Pfr. in Z. f. M.* 1847, p. 107, n. 8; *Consp.* n. 94; *Gray, Cat. Cycl.* p. 17, n. 9; *Pfr. Pneum. Mon.* p. 70.

Variety; *Cyclostoma Aurora*, Benson, in *Ann. & Mag.* 2nd ser. viii p. 186 (*Pfr. Ic.* t. 50, f. 11-13.)

*Hab.* India; Khasya Hills.

(1449) *Cyclophorus Jerdoni*.

Shell depressed turbate, decussated above by very crowded, raised and wrinkled lines and oblique striæ, more slightly decussated beneath; colour whitish, painted with angular chestnut coloured flames above, and till the middle of the lower surface, surrounded by a pale peripheral band, which is articulated with alternate stripes; spire depressed, with the apex prominent; whorls 5, convex, the last one depressed and flattened near the suture, which is distinct; rather angulated at its periphery; umbilicus middle sized, deep, open, showing two whorls; aperture scarcely oblique, nearly circular, angulate above; peristome rather expanded, thickened, whitish, with the margins united by a thick deposit, columellar margin rather reflected. Operc.? Height 20, greatest breadth 35, least br. 28 mill. (B.)

*Cyclostoma Jerdoni*, Benson, in *Ann. & Mag.* 2nd ser. viii 1851, p. 185; *Pfr. Ic.* n. 413, t. 50, f. 1-3.

*Cyclophorus Jerdoni*, *Pfr. Consp.* n. 95; *Pneum. Mon.* p. 71.

*Hab.* India. The Neilgherries Mountains (Jerdon).

(1450) *Cyclophorus zebrinus*.

Shell depressed-turbinate, rather solid, keeled,

sculptured with oblique, somewhat scaly striæ, and with several raised spiral ribs on the upper side, fulvous, irregularly painted with broad chestnut-coloured spots and waving whitish stripes; spire turbinate, blunt; whorls 5, moderately convex, the last one broad, convex beneath, rather compressed round the umbilicus, which is narrow and funnel-shaped; aperture rather oblique, circular, blueish inside; peristome white, double; inner edge continuous, expanded; outer edge thickened, reflected, affixed. Operc. ? Height 21, greatest breadth 34, least br. 27 mill.

*Cyclostoma zebrinum*, Benson, in *Journ. As. Soc.* v. 1836, p. 355; *Sow. Thes. Suppl.* p. 157, n. 176, t. 31, *A. f.* 237, 288; *Pfr. Ic.* n. 240, t. 34, f. 21-23.

*Cyclophorus zebrinus*, *Pfr. Consp.* n. 969; *Pneum. Mon.* p. 71.

*Hab.* India. Khasya Hills (Benson).

(1451) *Cyclophorus tigrinus*.

Shell turbinate, solid striate, chestnut-coloured, marked with yellowish oblique streaks and angulated flames; spire raised, with the apex rather pointed; whorls 6, convex, with several spiral ribs, of which three usually are stronger, last whorl smooth beneath; umbilicus middle-sized, open; aperture oblique, nearly circular, yellowish-inside; peristome thickened with concentric furrows, shortly reflected, with the margins united by an equal deposit, columellar margin dilated and expanded over the umbilicus. Operculum thin. Height 21, greatest breadth 32, least br. 27 mill.

*Cyclostoma tigrinum*, *Sow. in Proc. Z. S.* 1843, p. 30; *Thes.* n. 100, p. 126, t. 29, f. 201-204; *Reeve, Conch. Syst.* ii. t. 183, f. 10; *Pfr. Ic.* n. 56, p. 61, t. 8, f. 13-16, t. 16, f. 17-20.

*Cyclophorus tigrinus*, *Pfr. in Z. f. M.* 1847, p. 107, n. 13, *Consp.* n. 97; *Gray, Cat. Cycl.* p. 18, n. 13; *Pfr. Pneum. Mon.* p. 72.

*Hab.* The Philippine Islands (H. Cuming).

Seven varieties of this beautiful shell are noticed by Mr. Sowerby.

(1452) *Cyclophorus zebra*.

Shell perforate, globose-conic, thick, sculptured with spiral lines and several thread-like raised keels, marbled with brown and whitish spire turbinate, blackish towards the summit, with the apex rather-pointed; whorls 5, convex, the penult one somewhat bunchy, the last one gridled with one white band; aperture oblique, ovate-circular, whitish inside; peristome nearly straight, doubled, thickened externally, with the margins united by a sinuate deposit; columellar margin reflected often half covering the very narrow umbilicus. Operc. pale. Height 15, greatest breadth 17, least br. 15 mill.

*Cyclostoma zebra*, *Grateloup, in Act. Board.* xi. p. 441, t. 3, f. 9; *Pfr. Ic.* n. 138, p. 132, t. 13, f. 31, 32.

*Cyclostoma Philippinarum*, var. *Sow. Thes.* t. 29, f. 205 207.

*Cyclophorus zebra*, *Pfr. in Z. f. M.* 1847, p. 107, n. 16; *Consp.* n. 100; *Gray, Cat. Cycl.* p. 19, n. 15; *Pfr. Pneum. Mon.* p. 74.

Smaller, fulvous, with the ridges smaller, blunt, one of which, below the middle, is usually stronger; preistome nearly simple, expanded. Height 9, greatest breadth 12, least br. 10 mill. *Pfr. Ic.* t. 43, f. 19, 21)

Smaller, whitish, with interrupted chestnut-coloured streaks, and often with one brown or fulvous basal band; peristoma more distinctly doubled and expanded. (*Pfr. Ic.* t. 43, f. 21, 22.)

*Hab.* The Philippine Islands.

(1453) *Cyclophorus Philippinarum*.

Shell perforate, conic solid, sculptured above with crowded spiral ridges, fulvous, with chestnut-coloured spots and interrupted streaks, and with two white reddish-brown articulated bands, one of which runs along the suture, and the other at the periphery spire conic, rather pointed; whorls 6, scarcely convex, the last one somewhat angulated, rather flattened and smooth beneath; aperture oval, whitish inside; peristome straight, rather thickened, with the margins distant, united by a deposit; columellar margin dilated in the middle towards the outer side. Operc. typical. Height 9, greatest breadth 10, least br. 9 mill.

*Cyclostoma Philippinarum*, *Sow. in Proc. Z. S.* 1842, p. 83 (part); *Spec. Conch.* f. 180, 183?; *Thes.* p. 125, n. 99, t. 29, f. 206; *Pfr. Ic.* p. 42, n. 33, t. 5, f. 17, 18; t. 13 f. 32-34.

*Cyclophorus Philippinarum*, *Pfr. in Z. f. M.* 1847, p. 107, n. 17; *Consp.* n. 101; *Gray, Cat. Cycl.* p. 19, n. 16; *Pfr. Pneum. Mon.* p. 74, *Hab.* The Philippine Islands (H. Cuming).

(1454) *Cyclophorus Guimarasensis*.

Shell subglobose-conoidal, rather thin, slightly striate, chestnut-coloured, spotted with yellowish and articulated with the same along the suture; spire short, rather pointed; whorls 5, convex, the last one angulated above by several obsolete spiral ridges, keeled at its periphery, convex and uniformly dark brown beneath; umbilicus narrow, scarcely going through; aperture nearly circular, somewhat pearly inside; peristome rather thin, white internally, shortly expanded, with the margins approximate; columellar margin strongly arcuate, rather reflected, operc. ? Height 12, greatest breadth 16, least br. 14 mill.

*Cyclostoma Guimarasense*, *Sow. Thes.* p. 131, n. 115, t. 31, f. 274, 275; *Pfr. Ic.* p. 99, n. 96 t. 82, 8, 9.

*Leptopoma* ? *Guimarasense*, *Pfr. in Z. f. M.* 1847, p. 109, n. 13.

*Cyclophorus Guimarasensis*, *Gray, Cat. Cycl.* p. 18, n. 14; *Pfr. Consp.* n. 102; *Pneum. Mon.* p. 75.

*Hab.* The Philippine island Guimaras (H. Cuming).

(1455) *Cyclophorus*? *turbinatus*.

Shell depressed-turbinate, rather solid, sculptured with very crowded spiral striæ and several obsolete ridges, fulvous, with a reddish-brown articulated band along the suture which is moderately impressed; spire conoidal, with the apex pointed, horn-coloured; whorls 6, convex, somewhat angulated, the last one rather flattened beneath; umbilicus middle-size, open; aperture oblique nearly circular; peristome white, double; inner edge shortly produced; outer edge shortly expanded, with the margins united into an angle; upper margin somewhat dilated forward. Operc. typical. Height  $8\frac{1}{2}$ , greatest breadth 14, least br. 12 mill.

*Cyclostoma helicoides*, Sow. in *Proc. Z. S.* 1843, p. 65; *Thes.* p. 127, n. 103, t. 30, f. 245, 246. Not *Grateloup*.

*Cyclostoma turbinatum*, Pfr. in *Z. f. M.* 1846 p. 38; *I.* p. 100, n. 97, t. 13, f. 17, 18.

*Cyclophorus turbinatus*, Pfr. in *Z. f. M.* 1847, p. 107, n. 18; *Consp.* n. 103; *Gray. Cat. Cycl.* p. 19, n. 17; *Pfr. Pneum. Mon.* p. 75.

*Hab.* The Philippine island Bohol (H. Cuming).

(1456) *Cyclophorus*? *triliratus*.

Shell globose-turbinate, thin, chestnut-coloured, with paler spots and stripes, and with yellow flames along the suture, partially covered with a longitudinally wrinkled hairy periostraca; spire conic, pointed; whorls  $5\frac{1}{2}$ , moderately convex, increasing rapidly, the penult one bearing two; the last whorl thread-like fringed ridges, of which one is on the upper side, the second at the periphery, and the third near below the second; umbilicus, narrow, open; aperture oblique, nearly circular; peristome rather simple shortly expanded, whitish, callous internally, with the margins approximate joined by callus. Operc. ? Height 6, greatest breadth 8, least br. 7 mill.

*Cyclostoma triliratum*, Pfr. *Ic.* n. 386, t. 47, f. 8-10.

*Cyclophorus*? *triliratus*, Pfr. *Consp.* n. 104, p. 53; *Pneum. Mon.* p. 76,

*Hab.* Labuan (Gruner).

(1457) *Cyclophorus validus*.

Shell depressed-turbinate, thick, rather smooth, with numerous obsolete spiral ridges above, chestnut-coloured, with oblique angulated yellow streaks; spire conoidal, blunt; whorls 5, convex, the last one rather coarsely eccentrically striate beneath; aperture oblique, nearly circular, blueish-white inside; peristome white or orange-coloured, thickened and somewhat expanded, with the margins angularly united by a thin deposit; columellar margin free, dilated and reflected over the umbilicus, which is very narrow. Operc. typical, with the margin of the whorls lamellar. Height 26, greatest breadth 40, least br. 33 mill.

*Cyclostoma validum*, Sow. in *Proc. Z. S.* 1842, p. 82; *Thes.* p. 123, n. 93, t. 27, f. 132, 133; *Pfr. Ic.* p. 189, n. 85, t. 11, f. 910, t. 16, f. 15, 16.

*Cyclophorus validus*, Pfr. in *Z. f. M.* 1847, p. 107, n. 5; *Consp.* n. 105; *Gray. Cat. Cycl.* p. 16, n. 5; *Pfr. Pneum. Mon.* p. 77.

*Hab.* The Philippine islands. Leyte, Luzon, Samar, and Mindanao (H. Cuming).

(1458) *Cyclophorus indicus*.

Shell turbinate-conic, solid, sculptured with numerous slightly-raised spiral ridges, whitish, marbled with brown and brownish-red; spire turbinate, rather pointed; whorls  $5\frac{1}{2}$ , convex, the last one more distinctly keeled below the middle and marked with a blackish band, rather smooth beneath; aperture somewhat oblique, nearly circular; peristome double; inner edge orange-coloured, shortly expanded; outer edge white, expanded, triangularly dilated above, with the columellar margin dilated, reflected, half covering the narrow umbilicus. Height 25, greatest breadth 38, least br. 32, mill.

*Cyclostoma indica*, Desh. in *Belanger Voy.* p. 415, t. 1, f. 4, 5; *Desh. in Lam. Hist.* viii, p. 363, n. 28.

*Cyclostoma indicum*, Müll. *Synops.* p. 38; *Pfr. Ic.* n. 229, t. 33, f. 3, 4.

*Cyclophorus indicus*, Pfr. *Consp.* n. 106; *Pneum. Mon.* p. 77.

*Hab.* The Island of Elephanta, near Bombay.

(1459) *Cyclophorus linguiferus*.

Shell depressed-turbinate, thick, obsoletely spirally striate, fulvous with angular brown spots; spire rather raised, with the apex blunt; whorls 5, convex, the last one ventricose beneath; umbilicus middle-sized, open; aperture nearly perpendicular, circular, milk-white inside; peristome rather thickened, doubled, broadly bordered with fulvous internally, with the upper margin scarcely expanded; columellar margin dilated into a semilunar lamina, which is narrowly protracted downward. Operc. typical, with five nearly equal volutions. Height 22, greatest breadth 32, least br. 25 mill.

*Cyclostoma linguiferum*, Sow. in *Proc. Z. S.* 1843, p. 31; *Thes.* p. 125, n. 98, t. 29, f. 980, *Pfr. I.* p. 168, n. 181, t. 23, f. 1, 3.

*Cyclophorus linguiferus*, Pfr. in *Z. f. M.* 1847, p. 107, n. 10; *Consp.* n. 107; *Gray. Cat. Cycl.* p. 19; n. 19, *Pfr. Pneum. Mon.* p. 78.

*Hab.* The Philippine Island of Bohol (H. Cuming).

(1460) *Cyclophorus canaliferus*.

Shell depressed-turbinate, solid, sculptured above and beneath with crowded spiral striæ, and with 7-8 blunt spiral ridges above, chestnut-coloured, spotted with white, and bearing an articulated white band along the suture, which is deeply channelled; with a whitish peripheral band, below which the shell is uniformly chestnut,

coloured, pale beneath; spire shortly raised, rather blunt; whorls 5, convex, the last one rather disjoined; umbilicus middle-sized, open; aperture small, rather oblique, nearly circular, shining and whitish inside; peristome thickened, shortly reflected, continuous, with the columellar margin expanded into a free, rather semicircular lamina. Operc. typical. Height 13, greatest breadth 26, least br. 22 mill.

*Cyclostoma canaliferum*, Sow. in *Proc. Z. S.* 1843, p. 81; *Spec. Conch.* f. 195, 196; *Thes.* p. 115, n. 71, t. 27, f. 140, 141; *Pfr. Ic.* p. 40 n. 32, t. 5, f. 14, 16.

*Cyclophorus canaliferus*, *Pfr. in Z. f. M.* 1847, p. 107, n. 14; *Consp.* n. 108; *Gray. Cat. Cycl.* p. 19, n. 13; *Pfr. Pneum. Mon.* p. 78.

Pale, spotted along the suture with chestnut, brown, and banded with the same below the middle.

Pale yellowish, with the spire reddish, and the last whorl marked with a single chestnut-coloured basal band.

With the lamina of the columellar margin less dilated, not semicircular.

*Hab.* The province Tayabas, Island of Luzon (H. Cuming); var. Borneo.

(1461) *Cyclophorus lingulatus*.

Shell somewhat depressed-conoidal, rather thin, nearly smooth, chestnut-coloured, with white articulated bands along the suture and at the periphery; spire short, acuminate; whorls 5, scarcely convex, the last one angulated above by 3—4 blunt spiral ridges, usually sharp-keeled at its periphery, convex beneath; umbilicus middle-size, funnel-shaped; aperture scarcely oblique, rather circular, blueish inside; peristome continuous, usually double; inner edge sharp, scarcely prominent; outer edge thickened, with the left margin surrounded with a wing, which is dilated above in a tongue-shaped lamina. Operc. typical, rather flat. Height 16, greatest breadth 21, least br. 18 mill.

*Cyclostoma lingulatum*, Sow. in *Proc. Z. S.* 1843, p. 64; *Thes.* p. 126, n. 101, t. 29, f. 203, 210; *Pfr. Ic.* p. 148, n. 182, t. 23, f. 6, 10.

*Cyclophorus lingulatus*, *Pfr. in Z. f. M.* 1847, p. 107, n. 15; *Consp.* n. 109; *Gray. Cat. Cycl.* p. 20, n. 20; *Pfr. Pneum. Mon.* p. 79.

*Hab.* The Philippine islands Siquijor, Bohol, Zebu (Cuming).

(1462) *Cyclophorus fulguratus*.

Shell depressed, turbinate, solid, obliquely substriate, very closely decussated under the lens, white, very elegantly painted above with angulated chestnut-coloured streaks; spire turbinate, with the apex rather blunt, horn coloured; whorls 5, convex, the last one rounded, with a white peripheral band, below which is another of blackish chestnut-colour; white round the umbilicus, which is narrow and scarcely going through; aperture slightly oblique, rather circular,

grayish and shining inside; peristome simple fulvous, interrupted with the margins united by a thin deposit, right and basal margin equally expanded; columellar margin dilated and expanded over the umbilicus. Operc. ? Height 19, greatest breadth 29, least br. 23 mill.

*Cyclostoma fulguratum*, *Pfr. in Proc. Z. S.* 1851; *Ic.* n. 361, t. 45, f. 9, 10.

*Cyclophorus fulguratus*, *Pfr. Cons.* n. 110, p. 45; *Pneum. Mon.* p. 80.

*Hab.* Ava.

Shell subturbinat; peristome expanded; axis imperforated or quite covered.

(1463) *Cyclophorus turbo*.

Shell top-shaped, rather thin, nearly smooth, white or yellowish, marbled with chestnut-coloured spots and stripes; spire turbinate, with the apex rather pointed; whorls 5, moderately convex, the last one angulated, sometimes distinctly keeled, rather flat beneath; aperture oblique, roundish, rather quadrangular, whitish inside; peristome thickened, slightly reflected, white, with the margins distant, united by a very thin callus; columellar margin expanded above into a lamina, which is quite appressed on and covers the umbilicus; basal margin terminating towards the columella into a prominent knot. Operculum yellowish horny. Height 16, greatest breadth 25, least br. 21 mill.

*Trochus turbo*, *Chemn. Conch. Cub.* ix 2. p. 53, t. 122, f. 1059.

*Helix turbo*, *Gmel. Syst.* p. 3642, n. 232.

*Cyclophorus turbo*, *Pfr. in Z. f. M.* 1847, p. 108, n. 19. *Consp.* n. M.; *Gray, Cat. Cycl.* p. 20, n. 21. *Pfr. Pneum. Mon.* p. 80.

*Hab.* India, Tranquebar, and Coromandel (Chemnitz), Sumatra (Sowerby, Gray), Nicobar (Morch).

(1464) *Cyclophorus Amboinensis*.

Shell turbinate-depressed, solid, smooth, chestnut-coloured fulvous, sprinkled with white spots forming an interrupted band at the periphery; spire convexly conoidal, rather blunt; whorls  $4\frac{1}{2}$ , convex, the last one rounded, paler beneath; umbilicus narrow, open; aperture rather oblique, nearly circular, pale inside; peristome simple, somewhat thickened, almost imperceptibly expanded, with the margins united above into a slight angle. Operc. ? Height 10, greatest breadth 18, least br. 15 mill.

*Cyclostoma Amboinense*, *Pfr. in Proc. Z. S.* 1852; *Ic.* n. 400, t. 48, f. 20-22.

*Cyclophorus Amboinensis*, *Pfr. Pneum. Mon.* p. 82.

Smaller, chestnut-coloured, with indistinct pale stripes and bands; height  $8\frac{1}{2}$ , greatest

## MOLLUSCA.

breadth 14, least br.  $11\frac{1}{2}$  mill (*Pfr. Ic. t. 48 f. 23, 24.*)

*Hab.* Amboina.

(1465) *Cyclophorus ? caeloconus*.

Shell turbinate, thin, sculptured with crowded and rough radiating striæ, olivaceous yellowish, with a single reddish brown band below the periphery, and waving radiating streaks; spire conoidal, with the apex rather pointed; suture well impressed; whorls  $4\frac{1}{2}$ , very convex, last cylindrical; aperture oblique, ovate circular; peristome thin, sharp; umbilicus deep, showing all the whorls. Operc. ? Height 9, greatest breadth 13, least br. 11 mill. (*Bens.*)

*Cyclophorus caeloconus*, *Benson in Annals & Mag. 2nd, ser viii, 1851, p. 119; Pfr. Ic. n. 416, t. 50, f. 9, 10.*

*Cyclophorus ? caeloconus*, *Pfr. Consp. n. 113; Pneum. Mon. p. 83.*

*Hab.* India, the Neilgherries Mountains (*Jerdon.*)

(1466) *Cyclophorus ? obligatus*.

Shell small, thick, nearly globular, ash gray, narrowly perforate, girdled on both sides with equal sharp furrows and slight ribs, decussated by very minute striæ of growth; spire pointed; whorls 5, rounded; aperture small, ovate; peristome simple, thick. Height  $\frac{3}{8}$ , breadth  $\frac{5}{16}$  inch (*G.*)

*Cyclostoma obligatum*, *Gould, in Proc. Bost. Soc. 1847, p. 205; Exped. Shells, p. 38, ed. 1851, p. 104, f. 119.*

*Cyclophorus ? obligatus*, *Pfr. Consp. n. 117; Pneum. Mon. p. 84.*

*Hab.* The Island of Matea.

(1467) *Cyclophorus parvus*.

Shell depressed turbinate, rather thin, slightly striate, with 4 or 5 obsolete keels, fulvid whitish, with radiating brownish streaks; spire turbinate, with the apex rather pointed, horny; whorls 5-6, convex, the last one somewhat depressed, usually furnished with a more distinct keel round the funnel shaped umbilicus; aperture oblique, nearly circular; peristome rather simple, straight, with the margins united by a short deposit, which is somewhat emarginate; right margin forward, arcuate, prominent. Operc. horny, thick. Height  $5\frac{1}{2}$ , greatest breadth 9, least br.  $7\frac{1}{2}$  mill.

*Cyclostoma parvum*, *Sow. in Proc. Z. S. 1843, p. 66, Thes. n. 29, p. 101, t. 31, f. 254, 255; Pfr. Ic. n. 98, p. 100, t. 13 f. 15, 16.*

*Cyclophorus, parvus*, *Gray, Catal. Cycloph. p. 23, n. 37; Pfr. Consp. n. 118; Mon. p. 85.*

Smaller, brownish; height 3, greatest breadth 5, least br. 4 mill.

*Hab.* The Philippine Islands, Zebu and Panay (*H. Cuming*)

(1468) *Cyclophorus ? flavus*.

Shell conically globular, thick, yellow, closely sculptured with spiral furrows; spire conoidal rather pointed; whorls  $4\frac{1}{2}$ , convex, the last one

## MOLLUSCA.

ventricose; umbilicus extremely narrow, not going through; aperture ovate, slightly angulated above; peristome simple, blunt, with the margins joined by a deposit on penult whorl; columellar margin flattened. Operc. horny (*Bord.*) Height 7, greatest breadth 8, least br.  $6\frac{1}{2}$  mill.

*Cyclostoma flavum*, *Borderip, in Proc. Z. S. 1832, p. 59; Mull. Synops. p. 38; Sow. Thes. n. 55, p. 109, t. 24, f. 70; Pfr. Ic. n. 14, p. 23, t. 3, f. 9-11.*

*Cyclophorus Woodianus*, *Pfr.* in *Z. f. M.* 1847, p. 108, n. 28; *Consp.* n. 126; *Gray. Cat. Cycl.* p. 21, n. 26; *Pfr. Pneum. Mon.* p. 88.

*Hab.* Luzon (H. Cuming).

(1472) *Cyclophorus Charpentieri*.

Shell depressed-turbinate, rather solid, sculptured above with close-set spiral striae and 4-5 blunt thread-like ridges, yellowish, with horny-brown marble paintings, and along the suture with a series of rather square chestnut-coloured spots, and with a broad brown band below the peripheral keel; spire shortly turbinate, with the apex rather blunt; whorls  $4\frac{1}{2}$ , enlarging rapidly, the last one somewhat depressed, nearly smooth beneath; umbilicus middle-sized; aperture oblique, rather circular, slightly angular above, flesh-coloured inside; peristome yellowish or reddish, continuous, shortly affixed, produced anteriorly, into a concentrically-striated tube. Height 15, greatest breadth 28, least br. 23 mill.

*Cyclostoma Charpentieri*, Mousson, *Jav. Mool.* p. 56, t. 6, f. 3.

*Cyclostoma involvulus*, var? *Pfr. Ic.* p. 30, t. 8, f. 10-12.

*Cyclophorus Charpentieri*, *Pfr. Consp.* n. 127; *Pneum. Mon.* p. 89.

*Hab.* Java.

*Note.* This shell differs from *C. involvulus* by its more depressed shape; the spiral ridges are more raised, the umbilicus wider, the aperture smaller, &c. It is more turbinate than *C. Woodianus*, and has more distinct keels, the umbilicus is smaller, the aperture more oblique, and the inner edge of the peristome is produced into a tube, which is elongate on the right, and shorter on the left side.

(1473) *Cyclophorus appendiculatus*.

Shell depressed, solid, sculptured with crowded raised spiral lines; 4-5 of which are a little stronger; whitish, with brownish marble painting, with a series of large, rather square, chestnut-coloured spots along the channelled suture, and with a pale band above the keel, which is not very distinct, and articulated with brown spots; spire very shortly conoidal, with the apex rather blunt, horny; whorls  $4\frac{1}{2}$ , enlarging rapidly, the last one broadly depressed near the suture; umbilicus wide open; aperture oblique, circular; peristome continuous, shortly affixed, equally expanded all round, with the left margin expanded into a tongue-shaped appendix. Height 15, greatest breadth 34, least br. 27 mill.

*Cyclostoma appendiculatum*, *Pfr.* in *Proc. Z. S.* 1851; *Ic.* n. 360, t. 45, f. 7. 8.

*Cyclostoma canaliferum*, var. Sow. *Thes.* t. 27, f. 142?

*Cyclophorus appendiculatus*, *Pfr. Consp.* n. 128, p. 54; *Pneum. Mon.* p. 90.

*Hab.* Philippine Islands.

(1474) *Cyclophorus Bairdi*, *Pfr.*

Shell depressed, nearly discoidal, solid, with close set spiral striae, fulvid-yellowish, painted with very numerous oblique angular chestnut-coloured stripes; spire scarcely raised, a little prominent in the middle; whorls  $4\frac{1}{2}$ , moderately convex, the last one somewhat depressed, very obtusely angulated and marked with a chestnut-coloured band at its periphery; umbilicus open, occupying a little more than one-third of the whole diameter; aperture oblique, roundish, rather angular, white inside; peristome rather simple, continuous, shortly affixed, slightly expanded, and produced above into an indistinct angle. Height 9, greatest breadth 26, least br. 20 mill.

*Cyclostoma Bairdi*, *Pfr.* in *Proc. Z. S.* 1852; *Ic.* n. 399, t. 48, f. 17-19.

*Cyclophorus Bairdi*, *Pfr. Pneum. Mon.* p. 91.

*Hab.* Ceylon.

(1475) *Cyclophorus stenostomus*.

Shell depressed, discoidal, solid, sculptured with very crowded winkled striae, chestnut-coloured, with whitish or fulvous spots and flames; spire rather flat; whorls 4-5, moderately con-

vex, enlarging rapidly, the last one slightly descending anteriorly; umbilicus wide and deep; aperture very oblique, irregularly roundish, slightly angular above, blueish inside; peristome whitish, blunt, double, the outer edge interrupted, straight, thickened; inner edge continuous, with the part adjacent to the penult whorls rectilinear. Height 6, greatest breadth 16, least br.  $12\frac{1}{2}$  mill.

*Cyclophorus stenostoma*. *Sow. Thes.* n. 13. p. 95. t. 31. f. 261; *Pfr. Ic.* n. 159, p. 149. t. 20. f. 23-25.

*Cyclophorus stenostoma*, *Pfr. in Z. f. M.* 1847. p. 108, n. 34; *Consp.* n. 131; *Gray. Cat. Cycl.* p. 21. n. 29; *Pfr. Pneum. Mon.* p. 92.

Larger; height 9, greatest breadth 26, least br. 21 mill. (*Pfr. Ic.* t. 20. f. 18. 19.)

*Hab.* Arabia, (Powis), India, Neilgherries, (Jerdon), the var. from Cochin-China?

(1476) *Cyclophorus loxostomus*.

Shell depressed, discoidal, rather solid, closely sculptured with thread-like striae, fuscous-fulvid-varied with paler spots; spire flat, with the subtle apex not prominent; whorls 5, moderately convex, increasing gradually, last rounded, dilated anteriorly, not descending; umbilicus broad, bowl-shaped, forming more than one-third of the total breadth; aperture diagonal, rather circular, pearly within; peristome continuous, shortly affixed, straight, indistinctly doubled, scarcely thickened. Height 4, greatest breadth  $13\frac{2}{3}$ , least br. 11 mill.

*Cyclostoma loxostomum*, *Pfr. in Proc. Z. S.* 1852; *Ic.* n. 406, t. 49. f. 11-13.

*Cyclophorus loxostomus*, *Pfr. Pneum. Mon.* p. 93.

*Hab.* Ceylon (Mr. Lear).

(1477) *Cyclophorus alternans*.

Shell conoidally depressed, rather thin, sculptured with crowded alternatively smaller and stronger sharp ridges, not shining, white, with a pale yellowish deciduous periostraca; spire very shortly conoidal, with the apex rather blunt; suture slightly channelled; whorls 5, moderately convex, last rounded; umbilicus middle-sized, conic; aperture little oblique, rather circular; peristome simple, straight, with a brownish edge, rather continuous, with the margins joined on the penult whorl by a shining callus. Operculum membranaceous, wax coloured. Height 10, greatest breadth 20, least br. 16 mill.

*Cyclostoma alternans*, *Pfr. in Proc. Z. S.* 1851; *Ic.* n. 324, t. 41, f. 30-32.

*Cyclophorus alternans*, *Pfr. Consp.* n. 134, p. 55; *Pneum. Mon.* p. 94.

*Hab.* Madagascar.

(1478) *Cyclophorus annulatus*.

Shell much depressed, nearly discoidal, rather solid, with slightly-wrinkled striae, white, with obsolete brownish spots above, and a single band below the periphery, covered with a thin, olivaceous, horn-coloured periostraca; spire flat, with

the minute apex scarcely prominent; whorls  $4\frac{1}{2}$ , moderately convex, the last one slowly descending; umbilicus broad and deep; aperture oblique, ovate-roundish; peristome rather simple, imperceptibly expanded all round, with the margins approximate, joined by a short callus and forming a slight angle below the middle of the penult whorl. Operculum thin. Height 6, greatest breadth 18, least br. 15 mill.

*Cyclostoma annulatum*, *Troschel MSS.*; *Pfr. in Z. f. M.* 1847. p. 150; *Ic.* n. 175, p. 162, t. 22, f. 17-19.

Larger; height 8, greatest breadth  $23\frac{1}{2}$ , least br. 19, mill. (*Pfr. Ic.* t. 29, f. 14, 15.)

*Cyclostoma discus*, *Sowerby MSS. olim.*

*Hab.* Ceylon (Dr. Hoffmeister).

(1479) *Cyclophorus ravidus*.

Shell nearly discoidal, slightly shining, coarsely sculptured with crowded, slight, radiating striae, white, covered with an olivaceous-yellowish periostraca; spire scarcely raised, with the apex flattened, blunt; suture impressed; whorls 4, moderately convex, enlarging slowly, the last one cylindrical, scarcely descending anteriorly, obsolete spirally striate above near the suture; umbilicus wide, open; aperture oblique, circular; peristome thin, straight, with the margins joined by a thin deposit. Operculum horny. Height 7, greatest breadth 15, least br. 13 mill. (Bens.)

*Cyclostoma ravidum*, *Bens. in Ann. and Mag.* 2nd ser. viii. 1851, p. 190; *Pfr. Ic.* n. 417, t. 50, f. 14-16.

*Cyclophorus ravidus*, *Pfr. Consp.* n. 143; *Pneum. Mon.* p. 99.

*Hab.* S. India, the summits of the Neilgherries (Jerdon).

(1480) *Cyclophorus Phonotopicus*.

Shell depressed, nearly discoidal, thin, not shining, sculptured with coarse, sharp, radiating raised lines, and decussated near the suture, with impressed spiral striae, which are scarcely perceptible under a lens; colour reddish-brown, with angular, interrupted streaks; spire depressed, with the apex prominent; suture impressed; whorls  $4\frac{1}{2}$ , convex enlarging gradually; umbilicus deep, rather open; aperture circular; peristome slightly expanded and reflected, rather duplicate above outer edge somewhat angulated. Operculum horny with 7-8 volutions. Height 4, greatest breadth 12, least br. 10 mill.

*Cyclostoma Phonotopicum*, *Benson in Annals and Mag.* 2nd ser. viii. 1851, p. 190; *Pfr. Ic.* n. 419, t. 50, f. 20, 21.

*Cyclophorus Phonotopicus*, *Pfr. Consp.* n. 145, *Pneum. Mon.* p. 100, 417.

*Hab.* India, Darjiling, Sikkim-Himalayah.

*Cyclophorus Haughteni*: Theobald. *Moulmein.*

# MOLLUSCA.

*Cyclophorus Siamensis*. Sowerby, *Teria Ghat*. (Khasia Hills) 2 sp.

*Cyclophorus Pearsoni*. Benson, *Lacat*. (Khasia Hills) 2 sp.

*Cyclophorus fulguratus*. Pfr. *Thaïet-mio*. Rangoon.

*Cyclophorus expansus*. Pfr. *Tenasserim Valley*.

*Cyclophorus turobrulus*. Mull. *Midnapur*.

*Cyclophorus zebrinus*, Benson, *Naucalai*. (92° 30'E. 25°15'N).

*Cyclophorus aurantiacus*, Schum.—Tenasserim valley, not common.

*Cyclophorus Theobaldianus*, B.—Tenasserim valley, Maulmein, Thaïet-mio. This shell is nowhere common. In the Tenasserim valley it equals *C. aurantiacus* in size, but is easily distinguished by its more depressed form, colourless peristome, and flexuous striation. It has the greatest range of any Cyclostomatous shell of the provinces.

*Cyclophorus Haughtoni*, mihi.—n s. Testa, simili, *C. aurantiaco* solida nitidiuscula; carinata, superne saturate castanea; in decorticatis speciminibus, spiral lineis albidis ziczac variegata. Carina, catenata alternate albida et castanea. Periomphalo albido, fasciis nonnullis castaneis spirallibus lineato. Peristomate vix pallidissime ochraceo, ore interiori cærulescente—Maulmein.

Size—  
1.70 Major } diameter in inches. This shell  
1.85 Minor }

I have much pleasure in naming after Captain Haughton, to whom I am indebted for some fine shells. It occurs abundantly at the "farm caves," and is at once distinguished from all other Tenasserim Cyclophori, by its parti-coloured funiculate keel, which is not the result of abrasion but is best seen in specimens covered by the epidermis.

*Cyclophorus expansus*, Pfr.—Tenasserim valley. Not rare. This shell varies much in size, from  
1.70 0.80  
— to —  
1.26 0.65

*Cyclophorus affinis*, mihi.—b. s. Testa, subgloboso-turbinata: umbilicata, solidiuscula, castaneo-marmorata, band nitida, vix carinata, peristomate reflexo, forti, expansiusculo, distorto, pallidissime

flavescente, intus cærulescente —to—  
1.60 1.40  
1.36 1.12  
Maulmein.

This shell has no very marked character, unless a distortion in the peristome, one-third from its sutural margin, should prove constant. But two specimens were obtained, of which the measurements are given above.

*Cyclophorus fulguratus*, Pfr.—Thaïet-mio, Rangoon, very common. This fine shell is not rare at Rangoon and becomes very abundant near Thaïet-

# MOLLUSCA.

mio. It varies much in size and colour, some specimens are almost colourless

*Cyclostoma spiraculum* var., Sow. *Thes.* t. 31, f. 273?

*Pterocyclos rupestris* (part.), Gray, *Cat. Cycl.* 12, n. 3.

*Hab.* India, the Khasya Hills. (Benson).

## MOLLUSCA.

### (1487) *Pterocyclos Cumingi*.

Shell depressed, solid, slightly striate, shining, fulvous-yellow, with angular chestnut-coloured stripes, which are broader and darker near the periphery, so as to form two interrupted bands; spire flat; whorls 5, convex, the last one cylindrical, swollen anteriorly next the penult one into an elongated ridge, which is rounded above and surrounded by a furrow; umbilicus very broad; aperture a little oblique, nearly circular; pearly inside; peristome rather simple, white, thickened, reflected, interrupted above by a triangular incisure, and produced into a small inflected tongue. Operc. typical, with a small, blunt nucleus. Height 6, greatest breadth 32, least br. 22 mill.

*Pterocyclos Cumingi*, *Pfr. in Proc. Z. S.* 1851; and *Z. f. M.* 1851, p. 5;  *Ic. t.* 31, f. 6-8; *Consp. n.* 55; *Pneum. Mon.* p. 48.

*Hab.* Ceylon.

### (1488) *Pterocyclos bilabiatus*.

Shell depressed, nearly discoidal, slightly striate, whitish, with angular chestnut-coloured stripes; spire scarcely raised, with the apex rather blunt, blackish; whorls 5—5½, moderately convex, gradually increasing, the last one cylindrical with a brown band at the periphery; umbilicus broad; aperture oblique, circular; peristome double; inner edge nearly continued, straight, deeply notched above, outer edge vaulted into the shape of a cape near the penult whorl, with the right and basal margins deeply sinuous and undulated. Operc. typical. Height 8½, greatest breadth 20, least br. 17 mill.

*Pterocyclos bilabiatus*, *Bens. in Zool. Journ.* v. p. 462; *Journ. As. Soc.* v. p. 358; *Pfr. in Z. f. M.* 1847, p. 111, 1851, p. 4;  *Ic. p.* 93, t. 24, f. 11-14; *Consp. n.* 56; *Gray, Cat. Cycl.* p. 13, n. 6; *Pfr. Pneum. Mon.* p. 49.

*Cyclostoma bilabiatum*, *Sow. Thes. n.* 57, p. 110, t. 25, f. 81, 82; *Petit. in Journ. Conch. i.* p. 43.

*Hab.* India, Salem, near Madras (Heath, Sowerby.)

### (1489) *Pterocyclos Blandi*.

Shell orbiculate-depressed, whitish, with radiating, undulated, brownish-orange-coloured stripes, and one darker band at the periphery; whorls 4½, increasing rapidly, the last one suddenly dilated into a broad wing anteriorly; umbilicus very broad; aperture oblique; peristome rather duplicate; inner edge thickened, disjoined, and sinuous above; outer edge broadly expanded above, with a wing, which is disjoined, angulate anteriorly, descending, produced over the penult whorl, showing a sinus posteriorly. Greatest breadth 29, least br. 23 mill. *Bens.*

*Pterocyclos Blandi*, *Bens. in Ann. & Mag.* viii. 1851, *Aug. t.* 5, f. 1; *Pfr. Consp. n.* 58; *Pneum. Mon.* p. 49.

*Hab.* Island of Pulo Sussan, near Pulo Penang.

## MOLLUSCA.

### (1490) *Pterocyclos? biciliatus*.

Shell orbicular, flattened above, largely umbilicated beneath, very thin, nearly membranaceous, with sharp and hairy transverse striae, yellowish, painted with angular fulvous stripes; spire depressed; suture very deep; whorls 4½, cylindrical, with two obsolete angles, and two rows of incurved black hairs, the last one deflected; aperture oblique, circular (incomplete); the upper angle bearing a lamina with two channels. Height 7, greatest breadth 14.2, least br. 11.5 mill. (M.)

*Pterocyclos biciliatus*, *Monsf. Juv. Moll. p.* 49, t. 20, f. 9.

*Pterocyclos? biciliatus*, *Pfr. Consp. n.* 47; *Pneum. Mon.* p. 50.

*Cyclostoma biciliatum*, *Petit. in Journ. Conch. i.* p. 43.

*Hab.* India; Birmah.

This shell seems to be very nearly allied to *Cyclotus Taylorianus*, and perhaps it may be the same species.

### (1491) *Pterocyclos? incomptus*.

Shell depressed, solid, coarsely striate, opaque, white, with a deciduous brownish-horn-coloured periostraca; spire little raised, with the apex prominent; whorls 5, rapidly increasing, the last one cylindrical, obsoletely angulated; umbilicus very broad; aperture diagonal, nearly circular; peristome simple, with the columellar margin thickened, shortly affixed, separated by a deep notch from the upper one, which is dilated like a wing. Operc. Height 15, greatest breadth 40, least br. 32 mill.

*Cyclostoma incomptum*, *Sow. Thes. Suppl. n.* 133, p. 160; t. 31, A. f. 298, 299.

*Pterocyclos incomptus*, *Pfr. in Z. f. M.* 1851, p. 9;  *Ic. t.* 31, f. 1, 2; *Consp. n.* 45; *Pneum. Mon.* p. 42.

*Hab.* India? (Sowerby); Brazils (Cuming).

### (1492) *Pterocyclos brevis*.

Shell conoid-semiglobose, solid, slightly striate, a little shining, chestnut-coloured, with fulvous spots and stripes; spire short, rather blunt; suture broadly impressed, bordered; whorls 5, convex, the last one angularly, compressed round the broad and funnel-shaped umbilicus; aperture rather circular, white inside; peristome thickened, reflected, produced above in a triangular beak, which is closely pressed to the penult whorl, deeply channelled internally, and forms externally a broad, prominent, knot. Operculum blackish. Height 22, greatest breadth 36, least br. 30 mill.

*Lituus brevis*, *Martyn, Fig. of non-descar. Shells*, t. 21, c. ed. *Chenu, (Bibl. Conch. ii.)*, p. 21, t. 8, f. 2.

*Pterocyclos brevis*. *Pfr. in Z. f. M.* 1851. p. 9; *Consp.* n. 46; *Pneum. Mon.* p. 42.

*Hab.* India, Pulo Condore.

(1493) *Pterocyclos planorbulus*.

Shell depressed, discoidal, rather solid, striate, and irregularly foveate fulvous, with crowded angular reddish-brown radiating lines; spire flat, with the apex scarcely prominent; suture deep, channelled; whorls 5, moderately convex, the last one nearly cylindrical, with a blackish band at the periphery, white round the very broad umbilicus; aperture oblique, rather circular, bluish-white inside; peristome double; inner edge shortly expanded, indented above with a triangular notch; external edge scarcely broader, expanded, dilated into a disjoined wing above the notch. Operc. like that of *C. brevis*. Height 12, greatest breadth 39, least br. 31 mill.

*Hab.* Java? Borneo?

(1494) *Pterocyclos Troscheli*.

Shell orbiculate-depressed; whorls 4, slowly increasing, the last one rather dilated anteriorly; umbilicus very broad; peristome thickened, reflected, obsoletely sinuate anteriorly and above, with a cucollated wing, which is angulated and deflected anteriorly, adhering to the penult whorl. Operculum convex, horn-coloured. Greatest breadth 20, least br. 13 mill.

*Pterocyclos Troscheli*, *Bens. in Ann. & Mag.* viii. 1851, Aug. t. 5. f. 2; *Pfr. Consp.* n. 48; *Pneum. Mon.* p. 44.

*Hab.* Ceylon, Trincomalee (Bland.)

*Pterocyclos hispidus*. *Pearson. Teria Ghat.* (3 sp.).

*Cyclotus (fuscescens) rec.* 44 sp. also fossil.

(1495) *Cyclotus semistriatus*.

Shell turbinate-depressed, rather thin, upper side with crowded minute spiral lines, whitish, brownish-marbled; lower side smooth, whitish, with fine spiral furrows in the umbilicus, which is about half the diameter of the spire, conical, rather

# MOLLUSCA

acuminate; whorls 4-5, rounded, the last one scarcely descending anteriorly; aperture oblique, ovate-rounded; peristome straight, sharp; its margins on the penult whorl angularly joined by a short callus; right margin a little sinuate; columellar margin a little reflexed. Operc? Height  $8\frac{1}{2}$ , greatest breadth  $15\frac{1}{2}$ , least br. 11 mill.

*Cyclostoma semistriatum* *Sow. in Proc. Z. S.* 1843, p. 29; *Thes.* p. 91, n. 3, t. 23, f. 6, *Pfr. Ic.* p. 147, n. 156, t. 20, f. 10-12.

*Hab.* India. Poonah and Meemuch; also Ceylon?

(1496) *Cyclotus Fortunei*.

Shell turbinate-depressed, rather solid, faintly striated, fulvous, minutely marbled with chestnut-colour and with a single band of the same below the periphery; spire very short, turbinate, with a very small apex; suture simple; whorls  $4\frac{1}{2}$ , convex, last cylindrical, not descending; umbilicus conical, deep, forming about a quarter of the total breadth; aperture nearly perpendicular, rather circular, slightly angulated above; peristome simple; straight, shortly affixed to the penultimate whorl. Operculum typical, with the raised margin of the whorls threadlike. Height 7, breadth  $12\frac{1}{2}$  mill.

*Cyclostoma Fortunei*, *Pfr. in Proc. Zool. Soc.* 1852; *Ic.* n. 404, t. 49, f. 3-5.

*Cyclotus Fortunei*, *Pfr. Pneum. Monogr.* p. 30.

*Hab.* China, Shanghai (Mr. Fortune.)

(1497) *Cyclotus subdiscoideus*.

Shell depressed, rather solid, covered with crowded spiral lines on the whole surface, opaque of a pale flesh-colour, marked above with pale brownish spots, which are arranged in stripes; spire very shortly turbinate; with the apex nipple-shaped; whorls  $4\frac{1}{2}$ -5, convex, the last one nearly cylindrical, descending anteriorly; umbilicus broad; aperture nearly diagonal, circular, flesh-coloured inside; peristome simple, with the margins almost contiguous, upper margin sinuate, a little expanded; columellar margin shortly reflected. Operc. nearly flat, with the margins of the whorls sharply raised. Height 8, greatest breadth 17, least br.  $13\frac{1}{2}$  mill.

*Cyclostoma subdiscoideum*, *Sow. Thes. Suppl.* n. 184, p. 161, t. 31, B. f. 304, 305; *Pfr. Ic.* n. 325, t. 41, f. 33, 34.

*Cyclotus planorbulus*, *Gray. Cat. Cycl.* p. 8, n. 14, (part).

*Hab.* Philippine Islands (H. Cuming).

(1509) *Cyclotus Taylorianus*.

Shell depressed, nearly discoidal, thin, minutely striate, scarcely shining, whitish, with very elegant chestnut-coloured angulated stripes, and a fulvous-horn-coloured periostraca; spire nearly flat, with the apex horn-coloured, mucronate; suture deep; whorls 5, convex, the last one with two obsolete angles, each of which is furnished with a series of long black hairs, scarcely deflected anteriorly, bearing a small beak-like recurved

spiraculum on the suture, at the distance of 4 mill. behind the peristome; umbilicus very broad; aperture very oblique, nearly circular; peristome rather duplicate; inner edge expanded, affixed, sometimes indistinct; outer edge rather notched near the penult whorl; left margin shortly reflected; right margin broadly expanded; upper margin dilated, roof-like. Operculum like that of *C. variegatus*. Height 6, greatest breadth 17, least br. 13 mill.

*Cyclostoma Taylorianum*, *Pfr. in Z. f. M.* 1851, p. 7; *Ik. n.* 285, t. 38, f. 27-29, t. 43, f. 1-3.

*Cyclostoma Charbonnieri*, *Recher. in Journ. Conch.* 1851, ii. p. 214, t. 5, f. 12, 13.

*Cyclotus Taylorianus*, *Pfr. Consp. n.* 32; *Pneum. Mon.* p. 40

*Hab.* Borneo, Sarawak.

Compare with *Pterocyclos biciliatus*, *Mousson*. (1510) *Cyclotus rostellatus*.

Shell depressed, rather solid, slightly striate, horn-coloured, with fulminating chestnut stripes; spire very shortly turbinate, with the apex mucronate, black; whorls  $4\frac{1}{2}$ , convex, the last one descending anteriorly, bearing a beak-like recurved spiraculum 5 mill. behind the peristome; umbilicus moderately broad; aperture very oblique, nearly circular; peristome double, reddish; inner edge continued, a little expanded, affixed to the outer one, which is reflected into the plane of the aperture, very narrow below the penult whorl, shortly and convexly dilated above. Operc. typical. Height 5, greatest breadth 11, least br. 9 mill.

*Cyclostoma rostellatum*, *Pfr. in Z. f. M.* 1851, p. 8, *Ik. n.* 286, t. 38, f. 30-34.

*Cyclotus rostellatus*, *Pfr. Consp. n.* 44; *Pneum. Mon.* p. 40.

*Hab.* Singapore (saylor).

This species differs from *C. Taylorianus* by its spire, which is rather turbinate, by the more deflected last whorl, by the umbilicus, which is much narrower, by the more distinctly duplicate peristome, and by the greater distance of the spiraculum from the peristome. Compare with *Pterocyclos spiracellum*.

*Leptopoma (perlucidum)*, *rec.* 29 sp.

(1511) *Leptopoma vitreum*.

Shell globose-conical, thin, obliquely and slightly striate, decussated, under a lens, with crowded spiral lines, shining, pellucid, whitish or yellow, uniform or painted with brownish streaks, flames and bands; spire conoidal, rather pointed; whorls 5, convex, enlarging rapidly, the last one globular, with the axis very narrowly perforated; aperture oblique, roundish, subulate; peristome simple, sharp, shortly expanded, with distant margins; columellar margin slightly dilated and expanded, rather protracted in the middle into an angle. Height 14, greatest breadth 13, least br.  $13\frac{1}{2}$  mill.

*Cyclostoma vitrea*, *Lesson, Voy. de la Coquille*,

Smaller, rather solid, uniformly greenish white, with 5 whorls; height 8, greatest breadth 10, least br. 8 mill.

Shell uniformly glassy, or pale yellowish, with a single chestnut-coloured band and similar flame-paintings above; size like (*Pfr. Ic.* t. 12, f. 27-29).

*Cyclostoma lutea*, *Lesson Voy. Coquille*, p. 344, t. 13, f. 5?

*Hab.* New Guinea (Lesson), New Ireland and Moluccas (Quoy), Philippine Islands (H. Cuming) Java (Mousson); the var. from India, the Neilgherries Mountains.

(1512) *Leptopoma perlucidum*.

Shell globose-conical, thin sculptured with very close-set spiral striae, flesh-coloured-whitish, girdled very elegantly with greenish fulvid spiral lines; spire turbinate, pointed; whorls 5, convex, the last one ventricose; umbilicus narrow; aperture scarcely oblique, nearly circular, fulvous inside; peristome white, thin, broadly expanded with distant margins, columellar margin scarcely dilated, half covering the umbilicus. Height 13, greatest breadth 18, least br. 14, mill.

*Leptopoma multilabre*, *Pfr. in Z. f. M.* 1847, p. 109, n. 19; *Gray, Cat. Cycl.* p. 27, n. 17.

*Hab.* New Guinea (Lesson); New Holland (Lamarek).

(1518) *Leptopoma sericatum*.

Shell perforate, globose-conical, thin, pellucid silk-shining, sculptured with rather distant oblique lines and with 4-5 raised spiral lines above, glassy-whitish, with the ridges horn-coloured; spire turbinate, with the apex pointed, blackish; whorls 5, the upper ones somewhat convex, the last one ventricose, slightly keeled, marked below the keel, with a single chestnut-coloured band, sculptured beneath with several more obsolete spiral ridges; umbilicus excessively narrow, not pervious; aperture rather oblique, nearly circular, slightly emarginated; peristome simple, interrupted, thin, expanded into the plane of the aperture, with the columellar margin tongue-shaped in the middle. Height 9, greatest breadth 12, least br. 10 mill.

*Cyclostoma sericatum*, *Pfr. in Proc. Z. S.* 1851; *Ic.* n. 300, t. 40, f. 7, 8.

*Lepotoma sericatum*, *Pfr. Consp.* n. 154, p. 57; *Pneum Mon.* p. 108.

Smaller, with  $4\frac{1}{2}$  whorls, violaceous-fulvid, paler beneath; height  $7\frac{1}{2}$ , greatest breadth 10, least br. 8. mill. *Pfr. Ic.* t. 40, f. 11, 12.

*Hab.* Borneo (Taylor).

(1519) *Leptopoma Panayense*.

Shell perforate, globose-conical, very thin, nearly smooth, silk-shining, girdled with distant hair-like spiral ridges, pale fulvous, varied with chestnut-colour; spire short, conoidal, rather blunt; whorls 5, moderately convex, enlarging rapidly, the last keeled; aperture rather oblique, nearly circular, pearly inside; peristome simple, sharp, blueish-white, with a brownish edge, with the margins distant; right and basal margins arcuate, broadly and angularly expanded; columellar margins short, nearly rectilinear, reflected above, slightly ariculate at its base. Height 10, breadth 13 mill.

*Cyclostoma Panayense*, *Sow. in Proc. Z. S.* 1843, p. 62; *Thes.* n. 123, p. 134, t. 30, f. 239; *Pfr. Ic.* n. 162, p. 151, t. 20, f. 28, 29.

*Leptopoma Panayense*, *Pfr. in Z. f. M.* 1847, p. 108, n. 11; *Consp.* n. 156; *Gray, Cat. Cycl.* p. 25, n. 10; *Pfr. Pneum. Mon.* p. 108.

*Hab.* The Philippine Islands of Panay and Samar (H. Cuming).

(1520) *Leptopoma perplexum*.

Shell umbilicate, conoidal, rather thin, very minutely decussated under a lens, rather angulated, by equidistant obsolete keels slightly shining, uniformly whitish or varied with bands and spot of a yellow periostraca; spire short, conoidal, pointed; whorls  $5\frac{1}{2}$ , moderately convex, the last one more flattened beneath; aperture oblique,

## MOLLUSCA.

truncate-ovate, shining and white inside; peristome callus, thickened, expanded, with distant margins, joined by a rather thickened callus; columellar margin dilated and slightly reflected in the middle. Height 10, greatest breadth 16, least br. 13 mill.

*Cyclostoma perplexum*, *Sow. in Proc. Z. S.* 1844, p. 62; *Thes.* n. 127, p. 186, t. 30, f. 243, 244; *Pfr. Ic.* n. 136, p. 130, t. 16, f. 11, 12.

*Leptopoma perplexum*, *Pfr. in Z. f. M.* 1847, p. 109, n. 14; *Consp.* n. 157; *Gray, Cat. Cycl.* p. 25, n. 12; *Pfr. Pneum. Mon.* p. 109.

*Hab.* Island of Luzon, Albulug (H. Cuming).

(1521) *Leptopoma acutimarginatum*.

Shell depressed-turbinate, rather thin, slightly obliquely striate, olivaceous-brownish, marbled and banded with white; spire short, conical, rather pointed; whorls 5, moderately convex, the last one sharply keeled, more convex beneath; umbilicus narrow, scarcely pervious; aperture nearly circular, white and shining inside, with the external painting translucent; peristome not quite continuous, white or yellow, expanded all round, with the columellar margin slightly thickened and reflected. Height 18, greatest breadth 29, least br.  $23\frac{1}{2}$  mill.

*Cyclostoma acutimarginatum*, *Sow. in Proc. Z. S.* 1842, p. 80; *Thes.* n. 95, p. 124, t. 27, f. 138, 139; *Reeve, Conch. Syst.* t. 183, f. 7; *Pfr. Ic.* n. 133, p. 128, t. 15, f. 19-22.

*Leptopoma acutimarginatum*, *Pfr. in Z. f. M.* 1847, p. 109, n. 21; *Consp.* n. 158; *Gray, Cat. Cycl.* p. 27, n. 20; *Pfr. Pneum. Mon.* p. 110.

*Hab.* Island of Samar, Catbalonga (H. Cuming).

(1522) *Leptopoma helicoides*.

Shell top-shaped, thin, whitish, sometimes painted with minute brownish lines, or striped and marbled with chestnut-colour; spire conical, painted; whorls 6, rather flat, with 5-6 obsolete spiral ridges, the last one sharply keeled on its periphery, moderately convex on both sides, smooth beneath; umbilicus excessively narrow, not pervious; aperture oblique, ovate, rather circular, somewhat pearly inside; peristome thin, expanded and reflected, with distant margins; columellar margin slightly sinuate. Height 16, greatest breadth 21, least br.  $17\frac{1}{2}$  mill.

*Cyclostoma helicoides*, *Grateloup, in Act. Soc. Linn. Bord.* xi. p. 442, t. 3, f. 14; *Pfr. Ic.* n. 134, p. 129, t. 15, f. 25, 26, t. 16, f. 1-3.

*Cyclostoma Stainforthii*, *Sow. in Proc. Z. S.* 1842, p. 80; *Thes.* n. 129, p. 136, t. 29, f. 215, 216, t. 30, f. 217, *Reeve, Conch. Syst.* t. 183, f. 6.

*Leptopoma helicoides*, *Pfr. in Z. f. M.* 1847, p. 109, 29; *Consp.* n. 159; *Gray, Cat. Cycl.* p. 27, n. 19; *Pfr. Pneum. Mon.* p. 110.

# MOLLUSCA.

*Hab.* The Philippine Islands, Ticao, Masbate, Siquijor, Panay (H. Cuming)

## (1523) *Leptopoma insigne*.

Shell rather conoidal, very thin, membranous, silk-shining, horny olivaceous; spire conical, pointed; whorls 5, convex, the upper ones smooth, the two last obliquely striate, with four spiral ridges above, the last one very broad, sharply keeled on the periphery, ventricose beneath, with two scarcely prominent ridges; aperture little oblique, roundish, sublunate, somewhat pearly inside; peristome simple, shortly reflected, with distant margins; columellar margin white, slightly dilated, half covering the umbilicus, which is extremely narrow. Height 11, greatest breadth 15, least br. 12 mill.

*Cyclostoma insigne*, Sow. in *Proc. Z. S.* 1843, p. 62; *Thes.* n. 132, p. 138, t. 30, f. 232; *Pfr. Ic.* n. 107, p. 107, t. 12, f. 19, 20.

*Leptopoma insigne*, *Pfr. in Z. f. M.* 1847, p. 108, n. 10; *Consp.* n. 160; *Gray, Cat. Cycl.* 25, n. 9; *Pfr. Pneum. Mon.* p. 111.

*Hab.* Island of Mindoro, Calapan (H. Cuming).

## (1524) *Leptopoma ciliatum*.

Shell depressed turbinata, rather thin, slightly striate, chestnut-coloured, with fulvid streaks and spots; spire conoidal, with the apex pointed; whorls 5, moderately convex, the last one keeled on the periphery, furnished on the keel, with a single row of close set hairs, more flattened beneath; aperture oblique, nearly circular, whitish inside; peristome simple, slightly expanded, with distant margins; columellar margin shortly reflected. Height 8, breadth 12 mill.

*Cyclostoma ciliatum*, Sow. in *Proc. Z. S.* 1840 p. 65; *Thes.* n. 102, p. 127, t. 30, f. 237, 238; *Pfr. Ic.* n. 161, p. 150, t. 20, f. 26, 27.

*Leptopoma ciliatum*, *Pfr. in Z. f. M.* 1847, p. 109, n. 12; *Consp.* n. 161, *Gray, Cat. Cycl.* p. 25, n. 11; *Pfr. Pneum. Mon.* p. 112.

*Hab.* The province of South Camarinas, Island of Luzon (H. Cuming).

## (1525) *Leptopoma ciliferum*.

Shell turbinata conical, umbilicate, slightly keeled, thin transversely striate, reddish brown; spire very acuminate, with the suture perspicuous, whorls 6, rather flat on both sides, girdled above with five raised ridges, the last one rather inflated with the keel becoming obsolete, sculptured with scaly striae of growth, produced on the keel into long hairs, moderately convex beneath, furnished with slightly raised lines, which are more distinct towards the umbilicus; aperture nearly circular, angular above, with the margin double; outer edge rather membranaceous, reflected; inner edge straight. Height 9.4, greatest breadth 11, least br. 9 mill.

*Cyclostoma ciliferum*, *Mousson, Jar. Moll.* p. 56, t. 7, f. 3.

*Leptopoma ciliferum*, *Pfr. Consp.* n. 162; *Pneum. Mon.* p. 112.

*Hab.* Java.

# MOLLUSCA.

## (1526) *Leptopoma undatum*.

Shell very narrowly perforate, globose conical, thin, spirally and very closely striate, diaphanous whitish, painted irregularly with brownish waving streaks; spire elongate conic, with the apex rather pointed; whorls  $5\frac{1}{2}$ , scarcely convex, the last one large, sharply keeled below the middle, convex on both sides; aperture diagonal, ovate-roundish; peristome thin, with distant margins; right margin broadly reflected into the plane of the aperture; columellar margin shortly reflected. Height 12, greatest breadth 15, least br.  $11\frac{1}{2}$  mill.

*Cyclostoma undatum* *Metcalf, in Proc. Z. S.* 1851.

*Leptopoma undatum*, *Pfr. Consp.* n. 163; *Pneum. Mon.* p. 111.

*Hab.* Borneo.

## (1527) *Leptopoma fibula*.

Shell perforate, top-shaped, thin, slightly striate and obliquely faveolate, uniformly white or painted with horn-coloured angular stripes; spire conical, pointed; whorls 5-6, rather flat, girdled with unequal raised lines; last whorl rather convex, more distinctly keeled at the lower periphery; umbilicus narrow, half covered; aperture large, very oblique, truncatedly ovate; peristome expanded, with distant margins, joined by a thin callus; right margin almost rectilinear; basal margin slightly arcuate; columellar margin rather perpendicular, dilated and reflected. Height 16, greatest breadth 19, least br. 12 mill.

*Cyclostoma fibula*, Sow. in *Proc. Z. S.* 1843, p. 62; *Thes.* n. 125, p. 135, t. 30, f. 240, 242; *Pfr. Ic.* n. 135, p. 130, t. 15, f. 23, 24, t. 16, f. 4.

*Cyclostoma fibulum*, *Jay, Catal.* 1850, p. 255, n. 5864.

*Leptopoma fibula*, *Pfr. in Z. f. M.* 1847, p. 109, n. 15; *Consp.* n. 164; *Gray, Cat. Cycl.* p. 26, n. 13; *Pfr. Pneum. Mon.* p. 113.

*Hab.* The Island of Luzon (H. Cuming).

## (1528) *Leptopoma goniostomum*.

Shell perforate, conoidal, thin, sculptured with several scarcely raised spiral lines, pellucid, pale horn-coloured, variously striped and spotted with brown; spire conical, rather pointed; whorls 6, scarcely convex, the last one sharply keeled, a little more convex on both sides; aperture diagonal, ovate, rather triangular, somewhat pearly inside; peristome thin, shortly expanded, with distant margins; right margin rather rectilinear; columellar margin shortly dilated, not covering the very narrow umbilicus; basal margin arcuate. Operculum flat, with the edge of the volutions slightly raised. Height  $13\frac{1}{2}$ , greatest breadth 17, least br. 15 mill.

*Cyclostoma goniostoma*, Sow. in *Proc. Z. S.* 1843, p. 64; *Thes.* n. 131, p. 137, t. 30, f. 233, 234; *Reeve, Conch. Syst.* t. 183, f. 3; *Pfr. Ic.* n. 10, p. 18, t. 2, f. 3-7, t. 16, f. 5.

## MOLLUSCA.

*Leptopoma goniostoma*, *Pfr. in Z. f. M.* 1847, p. 109, n. 16; *Consp.* n. 165; *Gray. Cat. Cycl.* p. 26, n. 14; *Pfr. Pneum. Mon.* p. 114.

*Hab.* Island of Mindanao, Cagayan, Province of Misamis (H. Cuming).

(1529) *Leptopoma pileus*.

Shell perforate, conical, thin, whitish, sometimes clouded with very pale-brownish; spire pyramidal, pointed; whorls 6, rather flat, the last one sharply keeled, moderately convex beneath; aperture very oblique, ovate, rather angular on the side of the keel; peristome shortly expanded, having a white internal callus, with distant margins; columellar margin slightly dilated, half covering the narrow umbilicus. Height 15, greatest breadth 15, least br.  $13\frac{1}{2}$  mill.

*Cyclostoma pileus*, *Sow. in Proc. Z. S.* 1843, p. 31; *Thes.* n. 128, p. 136, t. 29, f. 196, 197; *Pfr. Ic.* n. 9, p. 18, t. 2, f. 3, 4; *Desh. Traite elem. Conch.* t. 82, f. 9, 10.

*Leptopoma pileus*, *Pfr. in Z. f. M.* 1847, p. 109, n. 17; *Consp.* n. 166; *Gray. Cat. Cycl.* p. 26, n. 15; *Pfr. Pneum. Mon.* p. 114.

*Hab.* Island of Luzon, the province of Flocos (H. Cuming).

(1530) *Leptopoma atricapillum*.

Shell perforate, globose-pyramidal, thin, diaphanous, whitish, variously striped and speckled with dark brown; spire pyramidal, with the apex pointed, black; whorls 6, convex, marked with several more or less obsolete spiral ridges; last whorl slightly convex below the strongest keel, nearly smooth; aperture oblique, roundish, sublunate, shining and white inside; peristome thin, expanded, with distant margins; columellar margin slightly sinuate, scarcely dilated above, half covering the very narrow umbilicus. Height 11, greatest breadth  $12\frac{2}{3}$ , least br. 11 mill.

*Cyclostoma atricapillum*, *Sow. in Proc. Z. S.* 1843, p. 64; *Thes.* n. 130, p. 137, t. 30, f. 230, 231; *Pfr. Ic.* n. 12, p. 20, t. 2, f. 11, 12, t. 16, f. 6, 7.

*Leptopoma atricapillum*, *Pfr. in Z. f. M.* 1847, p. 109, n. 18; *Consp.* n. 167; *Gray. Cat. Cycl.* p. 26, n. 16; *Pfr. Pneum. Mon.* p. 115.

*Hab.* Island of Mindora, Calapan (H. Cuming).

(1531) *Leptopoma regulare*.

Shell very narrowly perforate, conically-globular, thin, sculptured with rather crowded spiral edges, which are equal above, very closely spirally striate in the interstices, diaphanous, whitish, regularly speckled with fulvous spots; spire turbinate, with the apex pointed, pale horn-coloured; whorls  $5\frac{1}{2}$ , moderately convex, the last one more rounded, inflat, and more obsoletely spirally striate below the peripheral ridge; aperture oblique, roundish, sublunate; peristome interrupted, thin, white, shortly expanded, with the columellar margin rather angularly dilated at its lower extremity. Height 10, greatest breadth  $12\frac{1}{2}$ , least br. 10 mill.

## MOLLUSCA.

*Cyclostoma regulare*, *Pfr. in Proc. Z. S.* 1851; *Ic.* n. 298, t. 40, f. 3, 4.

*Leptopoma regulare*, *Pfr. Consp.* n. 168, p. 58; *Pneum. Mon.* p. 116.

*Hab.* The Philippine Islands.

Nearly allied to *L. atricapillum*, from which it differs by shorter spire, regular ridges, narrower umbilicus, etc.

(1532) *Leptopoma acuminatum*.

Shell perforate, conical turreted, rather thin, obliquely slightly striate, diaphanous, shining, whitish; spire elongated, with the apex acuminate, brownish; whorls  $6\frac{1}{2}$ , moderately convex, last rounded, keeled below the middle; aperture very oblique, truncatedly ovate; peristome sharp, expanded, with distant margins; columellar margin rather dilated and slightly reflected above, rather angularly thickened at its lower extremity. Height 13, greatest breadth 12, least br. 10 mill.

*Cyclostoma acuminatum*, *Sow. in Proc. Z. S.* 1843, p. 65; *Thes.* n. 133, p. 138, t. 30, f. 235; *Pfr. Ic.* n. 104, p. 108, t. 13, f. 11, 12.

*Leptopoma acuminatum*, *Pfr. in Z. f. M.* 1847, p. 108, n. 1; *Consp.* n. 169; *Gray. Cat. Cycl.* p. 27, n. 18; *Pfr. Pneum. Mon.* p. 116.

*Hab.* Island of Luzon, S. Juan (H. Cuming).

(1533) *Leptopoma elatum*.

Shell conical, rather thin, obliquely striate, crossed, under a lens, with distant raised spiral lines, scarcely diaphanous, whitish; spire conical, rather pointed; whorls  $5\frac{1}{2}$ , somewhat convex, the last one more rounded, subacutely keeled, more closely decussated beneath; umbilicus extremely narrow, not pervious; aperture diagonal, truncatedly ovate; peristome simple, with the margins distant, equally broad, angularly expanded; columellar margin scarcely narrower. Height  $10\frac{1}{2}$ , greatest breadth  $11\frac{1}{2}$ , least br. 10 mill.

*Cyclostoma elatum*, *Pfr. in Proc. Z. S.* 1851; *Ic.* n. 226, t. 32, f. 16, 17.

*Leptopoma elatum*, *Pfr. Consp.* n. 170, p. 58; *Pneum. Mon.* p. 117.

*Hab.* Ceylon.

(1534) *Leptopoma tenebricosum*.

Shell narrowly umbilicate, globose-conical, slightly striate, thin, rather pellucid, brownish, varied with darker stripes and clouds; spire turbinate rather blunt; whorls 4, very convex, last rounded, with a narrow yellow band on the periphery; aperture somewhat oblique, nearly circular, blueish, shining inside; peristome simple, straight, interrupted, with the columellar margin slightly reflected. Height 12, greatest breadth 14, least br. 12 mill.

*Cyclostoma tenebricosum*, *A. Adams & Reeve, Voy. Samarang, Moll.* p. 67, t. 14, f. 6; *Pfr. Ic.* n. 232, t. 33, f. 12, 13.

*Leptopoma tenebricosum*, *Pfr. Consp.* n. 171; *Pneum. Mon.* p. 117.

*Hab.* Borneo, Balambangan.

(1535) *Leptopoma Birmanum*.

Shell perforate, globose-conic, thin, sharply keeled, obliquely striate, decussated with very indistinct spiral lines, little shining, diaphanous, brownish-yellow, painted with broad angular streaks and interrupted bands of chestnut-colour; spire turbinate, rather blunt; whorls  $4\frac{1}{2}$ , moderately convex, last ventricose beneath; aperture somewhat oblique, rather quadrangular blueish, pearly inside; peristome simple, sharp, with the margins distant, straight (or in the complete state reflected?) Height 10, greatest breadth  $14\frac{1}{2}$ , least br. 10 mill.

*Cyclostoma Birmanum*, *Pfr. Consp.* p. 58; *Ik.* n. 385, t. 47, f. 4-7.

*Leptopoma Birmanum*, *Pfr. Consp.* n. 172, *Pneum. Mon.* p. 117.

*Hab.* British Burmah (Th. Philippi).

(1536) *Leptopoma halophilum*.

Shell globose-conical, thin, slightly striate, rather shining, fulvous, usually with a narrow, chestnut-coloured band; spire conical, rather pointed; whorls 5, rounded, last not descending, umbilicus narrow, not pervious; aperture somewhat oblique, nearly circular; peristome simple, straight, shortly interrupted, with the columellar margin scarcely reflected. Height 4-6, greatest breadth 6-7, least br.  $4\frac{2}{3}$ -6 mill.

*Cyclostoma halophilum*, *Benson. in Ann. and Mag.* 2nd ser. vii. p. 265; *Pfr. Ik.* n. 220, t. 31, f. 29-31.

*Leptopoma halophilum*, *Pfr. Consp.* n. 173; *Pneum. Mon.* p. 118.

*Hab.* Ceylon, point de Galle (Benson), Colombo (Templeman).

*Leptopoma aspirans*, *Bens. Tenasserim Valley.* (2 sp.).

*Lomastoma (cylindracem). rec.* 19 sp. also fos.

*Megalomastoma. Guilding.*

23.\* *M. gravidum*, B.—Maulmein. Very common.

24. *M. sectilabre*, Gould.—Yanglaw, on the Tenasserim. Very rare.

(1537) *Megalomastoma croceum*.

Shell perforate, oblong-turreted, rather solid, slightly obliquely striate, diaphanous, saffron-coloured; spire turreted-conical, with the apex rather pointed; whorls 7-8, moderately convex, the last one forming about  $\frac{2}{3}$  of the whole length; pale anteriorly; aperture angularly ovate, proceeding with its base beyond the axis, similarly coloured inside; peristome double; inner edge continuous, slightly expanded, affixed; outer edge thickened, expanded, white, shortly interrupted on the penultimate whorls. Operculum? Length 31, breadth 13 mill.

*Cyclostoma croceum*, *Sow. Thes.* n. 167, p. 150, t. 29, f. 190, 191; *Pfr. Ik.* n. 177, p. 164, t. 24, f. 15, 16.

*Cyclostoma Gouldianum*, *Petit, Journ. Conch.* i. p. 45.

*Hab.* The Philippine Island of Negros (H. Cuning).

(1539) *Megalomastoma sectilabrum*.

Shell perforate, oblong-turreted, rather solid, very minutely striate, opaque, brown; spire turreted, with the apex rather blunt; whorls 7, convex, the last slightly receding below the penultimate, rounded, not thread-keeled beneath; aperture oblique, with the base produced beyond the axis, ovate, roundish; peristome double; inner edge expanded, affixed, slightly effuse on the columellar side, outer edge shortly expanded, slightly interrupted on the penult whorl, dilated above and below the perforation. Length 23, breadth 10 mill.

*Cyclostoma sectilabrum*, *Gould, in Bost. Journ.* 1844, p. 459, t. 24, f. 10; *Pfr. Ik.* n. 178, p. 164, t. 24, f. 17, 18, t. 47; f. 11, i. 12.

*Megalomastoma sectilabrum*, *Pfr. in Z. f. M.* 1847, p. 109, n. 6; *Consp.* n. 195; *Pneum. Mon.* p. 133.

*Farcimen sectilabrum*, *Gray. Cat. Cycl.* p. 29, n. 3.

*Hab.* British Burmah, Tavoy.

(1540) *Megalomastoma funiculatum*.

Shell shortly rimate, turreted-oblong, thin, striate and irregularly foveolate, rather pellucid, brown; spire elongate, with the apex rather blunt; whorls 7, moderately convex, the last forming about  $\frac{3}{4}$  of the whole length, furnished beneath with a cord-shaped keel; aperture nearly perpendicular, scarcely produced with its base, circular; peristome continuous, flesh-coloured,

# MOLLUSCA.

shortly affixed, expanded and reflected all round. Length  $22\frac{1}{2}$ , breadth  $8\frac{1}{2}$  mill.

*Cyclostoma funiculatum*, Benson, in *Journ. As. Soc.* vii. 1838, p. 217; *Sow. Thes. Suppl.* n. 195, p. 166\*, t. 31-B. f. 316, 317; *Pfr. Ic.* n. 219, t. 31, f. 27, 28.

*Megalomastoma funiculatum*, Gray, *Cat. Cycl.* p. 31, n. 3; *Pfr. Consp.* n. 196; *Pneum. Mon.* p. 133.

*Hab.* Darjiling, Sikkim-Himalayah.

## (1541) *Megalomastoma pauperculum*.

Shell small, cylindrically turreted, shining, of an olivaceo-fulvous colour; spire rather obtuse, with six slightly-rounded volutions, very finely striated with the lines of growth (sometimes rendered slightly rugulose by erosion); suture distinct, rather deep; aperture nearly circular; peristome slightly thickened, rounded, and reflected, very slightly foliaceous and interrupted at the last volution; umbilicus small, surrounded by a somewhat obsolete raised line. Length 18, breadth 8 mill.

*Cyclostoma pauperculum*, *Sow. Thes. Suppl.* n. 196, p. 166\*, t. 31 B. f. 318; *Pfr. Ic.* n. 412, t. 49, f. 37, 38.

*Megalomastoma pauperculum*, *Pfr. Consp.* n. 198; *Pneum. Mon.* p. 134.

*Hab.* Bhotan Sikkim-Himalayah (Benson).

*Megalomastoma gravidum*, Benson. Moulmein. *Cataulus*.

## (1542) *Cataulus tortuosus*.

Shell deeply rimate, fusiform-oblong, rather solid, very minutely striate, shining, whitish; spire ovate-turreted, with the apex rather pointed, whorls 7, convex, the two penultimate ones broad, last whorl more slender, detached, protracted downward, furnished beneath with a thread-shaped keel, which becomes broader near the aperture; aperture perpendicular, rather circular; peristome continuous, white, reflected, distinctly channelled at its base, angulated externally, sinuate on the right side. Length 18, breadth 6 mill.

*Turbo tortuosus*, Chemn. *Couch. Cab.* xi. p. 158. t. 195, f. 1882, 1893.

*Megalomastoma tortuosum*, *Pfr. in Z. f. M.* 1847, p. 109, n. 3; *Gray. Cat. Cycl.* p. 30, n. 1.

*Cataulus tortuosus*, *Pfr. Consp.* n. 200; *Pneum. Mon.* p. 136.

*Hab.* The Nicobar Islands.

# MOLLUSCA.

## (1543) *Cataulus Templemani*.

Shell subperforate, oblong, rather fusiform, solid, striate, slightly shining, chesnut-coloured; spire oblong-turreted, with the apex rather pointed; whorls 8, moderately convex, the last furnished beneath with a sharp prominent keel, deeply striate round the umbilicus, which is very narrow; aperture circular, with the base slightly produced; peristome continuous, orange-coloured, shortly affixed above; right and left margins expanded and reflected; basal margin dilated downward, furnished with a canal, which is linear internally, and becomes broader at its termination. Length 20, breadth  $7\frac{1}{2}$  mill.

*Pupina Templemani*, *Pfr. in Proc. Z. S.* 1851, *Ic.* t. 31, f. 15, 16.

*Cataulus Templemani*, *Pfr. Consp.* n. 201; *Pneum. Mon.* p. 136.

*Hab.* Ceylon (Templeton).

## (1544) *Cataulus Layardii*.

Shell subperforate, oblong, rather fusiform, solid, sculptured with distinct arcuate striæ, pale straw-coloured; spire oblong-turreted, with the apex rather pointed; whorls 8, nearly flat, the last furnished with a raised and compressed basal keel, radiately ribbed round the narrow umbilicus; aperture perpendicular, nearly circular, prolonged at its lower part by a rather open canal; peristome continuous, white, shortly affixed above, double; inner edge prominent; outer edge thickened and reflected, produced at its base, into an angle and grooved by a channel which is narrow internally, broader at the aperture. Length  $17\frac{1}{2}$ , breadth 7 mill.

*Megalomastoma Layardii*, Gray (*Brit. Mus.*), *Cat. Cycl.* p. 31, n. 4.

*Pupina Templemani*, *Pfr. in Proc. Z. S.* 1851.

*Pupina Layardii*, *Pfr. Ic.* t. 31, f. 17, 18.

*Cataulus Layardii*, *Pfr. Consp.* n. 202; *Pneum. Mon.* p. 137.

Brownish, with the suture obsoletely whitish-denticulate.

*Hab.* Ceylon (Mr. Layard).

## (1545) *Cataulus pyramidatus*.

Shell subperforate, ovate-pyramidal, solid, marked with distinct, crowded slightly arcuate striæ silk-shining, dark chestnut-coloured; spire turreted with apex rather pointed; whorls  $7\cdot7\frac{1}{2}$ , moderately convex, the last not lessened, scarcely produced beneath beyond the axis; basal keel compressed, scarcely dilated anteriorly; space between the keel and umbilicus rather broad, more deeply striate, turgid in the middle; aperture nearly circular; peristome white, continuous, shortly affixed, thickened, expanded horizontally and slightly reflected, scarcely produced at its lower part, and grooved by a middle-sized channel. Length 23, breadth 10 mill.

# MOLLUSCA.

*Cataulus pyramidatus*, *Pfr. in Proc. Z. S.* 1852,  *Ic. t. 48, f. 11; Pneum. Mon. p. 137.*

Larger, with the basal part of the peristome singularly produced; length 29, breadth  $12\frac{1}{2}$  mill. (*Pfr. Ic. t. 48, f. 9, 10.*)

*Hab.* Ceylon.

(1546) *Cataulus eurytrema*.

Shell subperforate, oblong, rather fusiform, solid with slightly arcuated striæ, scarcely shining, chesnut-coloured; spire turreted, with the apex rather blunt; whorls  $8\frac{1}{2}$ , convex, last narrower, with the base obliquely produced beyond the axis; basal keel strong, compressed, dilated gradually, like a tube, towards the peristome; aperture circular; peristome flesh coloured, continuous, shortly affixed, thickened and reflected with the left part of the basal margin grooved by a large canal, which is rather circular, and is produced inwards into a filiform crevice. Length 26, breadth 10 mill.

*Cataulus eurytrema*, *Pfr. in Proc. Z. S.* 1852,  *Ic. t. 48, f. 12, 13; Pneum. Mon. p. 138.*

*Hab.* Ceylon.

(1547) *Cataulus Thwaitesi*.

Shell scarcely perforate, turreted, rather fusiform, solid, sculptured with crowded small longitudinal ribs, scarcely shining, violaceous-brown; spire ovate-turreted, with the apex rather pointed; suture impressed; whorls 7-7 $\frac{1}{2}$ , moderately convex, last a little lessened; basal keel very strong, compressed, spreading angularly, white; aperture perpendicular, circular; peristome double, white; inner edge deeply grooved at its lower part; outer edge emarginated on the penult whorl, otherwise thickened and reflexed, perforated at its base by a middle sized channel. Length 19, breadth 7 mill.

*Cataulus Thwaitesi*, *Pfr. in Proc. Z. S.* 1852,  *Ic. t. 49, f. 9, 10, Pneum. Mon. p. 138.*

*Hab.* Ceylon, (Mr. Thwaites.)

(1548) *Alycæus gibbus*.

Shell irregularly conical, inflated, rather thin, sculptured with longitudinal rib-like striæ, flesh-coloured grayish; spire regularly elongate, conical, with the apex rather blunt, orange-coloured or blackish; suture deep, simple; whorls 6, very convex, the last one protuberantly inflated laterally, contracted near the aperture, narrower anteriorly; umbilicus excentric, very narrow, scarcely pervious; aperture oblique, nearly circular; peristome double; inner edge shortly produced; outer edge shortly expanded, emarginated near the perforation. Height 8, greatest breadth 11, least br. 8 mill.

*Cyclostoma gibbum*, *Ferussac, Mus.; Eydoux in Guerin, Mag.* 1838, t. 17, f. 1; *Sow. Thes. n.* 135, p. 139, t. 30, f. 247, 248; *Pfr. Ic. n.* 108, t. 46, f. 28.

# MOLLUSCA.

*Alycæus strangulatus*, *Gray. Cat. Cycl. p. 28, n. 2; Pfr. Consp. n. 176; Pneum. Mon. p. 120.*

*Hab.* India. Landour.

(1550) *Alycæus constrictus*.

Shell perforate, ovate conic, smooth, with narrow, distant, oblique ribs, translucent, whitish or reddish brown; spire elongate conical, with the apex blunt; suture much impressed; whorls 4, rounded, the upper ones smooth, the following distantly ribbed, the last one sculptured with very crowded rib like striæ, strangulated behind the aperture, and broadly contracted anteriorly, with a retroversed sutural callus, like *L. strangulatum*, behind the constriction; aperture perpendicular, circular, equalling  $\frac{3}{4}$  of the whole length; peristome reflected all round. Operculum shelly, many whorled, with the suture inconspicuous. Height  $3\frac{1}{2}$ , breadth 2 mill.

*Cyclostoma constrictum*, *Benson. in Ann. and Mag.* 2nd. ser. xiii. 1851, p. 188, *Pfr. Ic. n.* 108, t. 46, f. 28.

*Alycæus constrictus*, *Pfr. Consp. n. 177, Pneum. Mon. p. 120.*

*Hab.* Darjiling Sikkim Himalayah.

*Alycæus pyramidalis*, B.—Therabuin hill, near the Tenasserim river. This pretty little shell appears confined to Therabuin hill, where it is not very common. It is of a delicate pink tint.

*Alycæus amphora*, B.—Maulmein and Tenasserim valley. Rare.

*Alycæus umbonalis*, B.—Akowtong. Not rare.

*Alycæus sculptilis*, B.—Thaïet-mio. Rare.

*Alycæus armillatus*, B.—Thaïet-mio. Rare.

*Alycæus prosectus*, B.—Teria Ghat. (vide March annals).

*Pupina*, rec. 8 sp.

(1555) *Pupinella pupiniformis*.

Shell open, perforate, oblong, regularly and crowdedly striate under a lens, brown; spire gradually tapering towards the rather pointed apex; whorls 7, moderately convex, the last shorter and narrower than the penultimate one; columella divided by an oblique, linear groove, which terminates externally into an open hole; aperture perpendicular, nearly circular; peristome broadly expanded and reflected, with the margins joined by a very thin callus; columellar margin flat, expanded, thickened round the hole and produced into a rounded keel, which sur-

rounds the umbilicus. Length 17, breadth  $6\frac{1}{2}$  mill.

*Cyclostoma pupiniforme*, Sow. in *Proc. Z. S.* 1842, p. 84; *Thes.* n. 174, p. 152, t. 28, f. 188.

*Pupina Sowerbyi*, *Pfr.* in *Z. f. M.* 1847, p. 110, n. 10; *Id.* p. 200, t. 27, f. 7, 8.

*Pupinella pupiniformis*, Gray. *Cat. Cycl.* p. 34; *Pfr. Consp.* n. 203; *Pneum. Mon.* p. 139.

*Hab.* Island of Luzon, the province of Cagayan (H. Cuming)

(1556) *Pupina Forbesi*.

Shell deeply and shortly rimate, pupa-shaped, solid, foveolate and wrinkled, opaque, fulvous-flesh-coloured; spire turgid in the middle, with the apex conoidal, rather blunt; whorls 6, the upper four convex, regular, the fifth flattened on the side of the mouth, the last much narrower, descending anteriorly, ascending near the aperture with the arcuate keel near the umbilical cleft; aperture nearly circular, with the base produced beyond the axis; peristome thick, fulvous-orange-coloured, reflected, with two channels; one very small at the insertion of the right margin, the second very deep and surrounded with thick callus between the arcuate body-margin and the left margin. Length 30, breadth 15 mill.

*Pupina grandis*, Forbes in *Voy. Rattlesnake*, *App.* p. 380, t. 2, f. 10, not Gray.

*Pupina Forbesi*, *Pfr. Consp.* n. 204; *Id.* t. 31, f. 19, 20; *Pneum. Mon.* p. 140.

*Hab.* The Louisiade Archipelago (Macgillivray).

(1557) *Pupina humilis*.

Shell scarcely subperforate, oblong-ovate, solid, little shining, pale brownish; whorls 6, the upper ones moderately convex, the last rounded, slender; aperture perpendicular, circular, with two channels; peristome thickened, expanded, with the right margin produced upwards, separated from the arcuate body-margin by a small sinus; columellar margin divided in the middle by a channel which runs backward arcuately, and is surrounded by thick callus. Length 16, breadth 7 mill.

*Pupina humilis*, Jacq. in *Ann. Sc. Nat.* 1841. *Hombr. & Jacq. Voy. Pol. Sud. Moll.* t. 10, f. 21-24; Sow. in *Proc. Z. S.* 1841, p. 103; *Thes.* n. 7, p. 18, t. 4, f. 2; Reeve, *Conch. *Pupina antiquata*, Sow. *Conch. Mon.* ed. ii. t. 526.

*Hab.* New Guinea. (Hombr. and Jacq.)

(1558) *Pupina Mindorensis*.

Shell imperforate, pupa-shaped, rather solid, very closely striate, silk-shining, brown; spire oblong-conical, with the apex rather pointed; suture deep, bordered; whorls 7, convex, the last one narrower, rounded; aperture rather circular, oblique, its base being produced beyond

the axis, sinuated above by a triangular callus, which is placed on the body of the penultimate whorl, near the insertion at the right margin; peristome broad, thickened, angularly reflected, with the right margin suddenly lessened near the upper channel; columellar margin flat, truncated in a right angle, forming an open channel, which is dilated backward. Length 11, breadth 5, mill.

*Pupina Mindorensis*, A. Adams & Reeve, *Voy. Samarang. Moll.* p. 57, t. 14, f. 2; *Pfr. Id.* t. 31, f. 21, 22; *Consp.* n. 206; *Pneum. Mon.* p. 141.

*Hab.* The southern part of Mindoro (Belcher).

(1559) *Pupina bilinguis*.

Shell oblong ovate, pellucid, shining, horn-coloured; spire tapering gradually towards the apex, which is rather blunt; suture impressed, scarcely callus; whorls 6, the upper three convex, closely striate, the following ones rather flat, smooth, the last forming a little more than one-third of the whole length; aperture perpendicular, rather circular, with two open ascending channels; upper channel formed by a strong, triangular, tongue-shaped lamina near the insertion of the right margin; peristome rather thickened, shortly expanded, with the columellar margin flat, tongue-shaped, sharp, forming the second channel with the basal margin. Length 10 breadth 5 mill.

*Pupina bilinguis*, *Pfr.* in *Proc. Z. S.* 1850, p. 97; *Consp.* n. 207; Forbes, in *Voy. Rattlesnake*, *App.* p. 374; *Pfr. Pneum. Mon.* p. 142.

*Hab.* The north-east coast of Australia, Cape York (Macgillivray); Blackwood Bay and Restoration Island.

(1560) *Pupina Thomsoni*.

Shell imperforate, pupa-shaped, extremely thin, smooth, pellucid, pale reddish horn-coloured; spire ovate-conical, with the apex rather blunt; suture not callus; whorls 6, the upper ones convex, the penultimate rather flat, the last narrow; aperture nearly circular, with two channels produced at its base beyond the axis; peristome slightly thickened, with the body-margin terminated on the right side into a tongue-shaped appendix, separated by a narrow equal sinus from the right margin, which is sinuate; columellar margin truncated, forming with the basal margin a channel, which is bordered by two callus bands diverging upwards. Length  $8\frac{1}{2}$ , breadth 4 mill.

*Pupina Thomsoni*, Forbes, in *Voy. Rattlesnake*, *App.* p. 381, t. 3, f. 2; *Pfr. Pneum. Mon.* p. 142.

*Hab.* Fitzroy Island, north-east coast of Australia (Macgillivray).

(1561) *Pupina bicanaliculata*.

Shell ovate-acuminate, rather thin, pellucid, smooth, shining, fulvous, or glassy; whorls 6, the last shorter than the spire, descending regularly; suture distinct impressed; aperture nearly

# MOLLUSCA.

perpendicular, circular, with two channels, the upper of which is formed by a small raised lamina on the body of the penultimate whorl near the insertion of the right margin; columella very narrowly carved obliquely; peristome simple, with the right margin indistinctly thickened. Length  $6\frac{1}{2}$ , breadth 4 mill.

*Pupina bicanaliculata*, Sow. in *Proc. Z. S.* 1841, p. 103; *Thes.* n. 9, p. 19, t. 4, f. 1; *Pfr. Ic.* p. 204, t. 27, f. 19, 20; *Gray. Cat. Cycl.* p. 33, n. 1; *Pfr. Consp.* n. 202; *Pneum. Mon.* p. 143.

*Hab.* The Philippine Islands of Zebu (H. Cuming.)

## (1562) *Pupina Keraudreni*.

Shell pupa-shaped, diaphanous, smooth, very shining, yellowish-white; apex rather blunt; whorls 5, the last shorter than the spire, descending obliquely; suture callous; aperture perpendicular, circular, with a slight upper channel formed by minute lamina on the body of the penultimate whorl, columella carved horizontally; peristome simple, blunt. Length  $6\frac{1}{2}$ , breadth  $3\frac{1}{4}$  mill.

*Pupina Keraudreni*, Vignard, in *Ann. Sc. Nat.* iii. p. 440, t. 11; Sow. in *Proc. Z. S.* 1841, p. 103; *Thes.* n. 8, p. 19, t. 4, f. 3; *Pfr. Ic.* p. 206, t. 27, f. 23, 24; *Gray, Catal. Cycl.* p. 33, n. 4; *Pfr. Consp.* n. 210; *Pneum. Mon.* p. 143.

*Pupina mitis*, Hinds, in *Ann. and Mag.* x. p. 83, t. 6, f. 7.

*Hab.* New Guinea (Vignard); New Ireland (Hinds); and Salomon Islands.

## (1564) *Registoma grande*.

Shell ovate-cylindrical, smooth, very shining, rather diaphanous, sulphur or lemon-yellow, or reddish; apex blunt; whorls 5, convex, the last one shorter than the spire, deviating, rather flattened, bordered anteriorly with chestnut-colour; suture impressed, rather simple; aperture parallel with the oblique axis, rather angularly circular; Columellar dilated, flat, with an oblique notch, forming on the edge a small open hole, and externally a slightly prominent ridge; peristome broadly expanded, blunt. Length  $11\frac{1}{2}$ , breadth  $7\frac{1}{2}$  mill.

*Pupina grandis*, Gray, in *Aun. Nat. Hist.* 1840, vi. p. 77.

## (1565) *Registoma pellucidum*.

Shell obliquely-ovate, very smooth, pellucid, fulvous; apex blunt; whorls  $5\frac{1}{2}$ , the upper ones depressed, the penultimate prominent, the last shorter than the spire, deviating, shortly ascending anteriorly; suture rather simple; columella flattened, curved backward, perforated by a channel, which is nearly covered and ends in an open hole; aperture parallel to the axis rather circular; peristome slightly thickened, shortly expanded. Length  $7\frac{1}{2}$ , breadth 5 mill.

*Pupina pellucida*, Sow. in *Proc. Z. S.* 1841, p. 102; *Thes.* n. 2, p. 17, t. 4, f. 18-20; *Pfr. Ic.* n. 202, t. 27, f. 17, 18.

*Hab.* The Philippine Islands of Luzon and Zebu (H. Cuming).

(1566) *Registoma simile*.

Shell ovate, rather elongate, smooth, shining, pellucid, pale fulvous; apex rather pointed; whorls 6, nearly flat, the last forming scarcely one-third of the whole length; suture linear, rather simple; columella thickened, vaulted, separated from the peristome by an oblique deep notch, terminating in an open hole, which is conspicuous on the back of the shell; aperture nearly circular, with its base slightly protracted, circular; peristome thickened, expanded, yellowish-white. Length 11, breadth  $5\frac{1}{2}$  mill.

*Pupina similis*, Sow. in *Proc. Z. S.* 1841, p. 102; *Thes.* n. 5, p. 18, t. 4, f. 4, 5; *Reeve, Conch. Syst.* t. 181, f. 3, 4; *Pfr. Ic.* p. 202, t. 27, f. 13, 14.

*Registoma simile*, Gray, *Cat. Cycl.* p. 32, n. 3; *Pfr. Consp.* n. 238; *Pneum. Mon.* p. 146.

*Hab.* Bolino, Island of Luzon, province of Zambales (H. Cuming).

(1567) *Registoma fuscum*.

Shell ovate-acuminate, highly polished, shining, pellucid, brownish-fulvous; whorls  $6\frac{1}{2}$ -7, convex, the last narrower than the penultimate, not equalling one-third of the total length; suture simple, slightly callus; columella short, rather convex, terminated by a rather horizontal notch, which ends in a triangular hole, not conspicuous on the back of the shell; aperture large, circular, nearly perpendicular; peristome dilated, flattened expanded, orange coloured or yellow, with the basal margin strongly arcuate. Length 11, breadth  $5\frac{1}{2}$  mill.

*Pupina fusca*, Gray, in *Ann. of Nat. Hist.* vi. 1840, p. 77.

*Pupina vitrea*, Sow. in *Proc. Z. S.* 1841, p. 102; *Thes.* n. 4, p. 10, t. 4, f. 6, 7; *Conch. Mon.* ed. ii. f. 524; *Reeve Conch. Syst.* t. 181, f. 1, 2; *Pfr. Ic.* p. 203, t. 27, f. 9-12; *Desh. Traite elem. Conch.* t. 82, f. 19, 20.

*Hab.* Luzon and Mindanao (H. Cuming).

(1568) *Registoma Nicobaricum*.

Shell imperforate, ovate-conical, rather solid, highly-polished, shining, pale reddish-yellow; spire convex, conical above, with the apex rather pointed; suture linear; whorls 5, scarcely convex, the last one descending obliquely, shortly, ascending near the aperture, rounded beneath; aperture nearly perpendicular, circular, marked with a minute callus knot near the insertion of the right margin; peristome simple, scarcely expanded; columellar margin slightly thickened, separated from the basal margin by a short rather ascending notch. Length 6, breadth 3 mill.

# MOLLUSCA.

*Pupina Nicobarica* (*Registoma*), *Pfr. in Proc. Z. S.* 1852; *Ic. t.* 48 f. 23-31; *Pneum. Mon.* p. 147.

*Hab.* The Nicobar Islands.

(1569) *Callia lubrica*.

Shell ovate-acuminate, smooth, shining, pellucid, fulvous glassy; whorls 5, moderately convex, the last much shorter than the spire, ascending anteriorly; suture impressed, callus; aperture nearly circular, with the base slightly produced beyond the axis; columella, short vaulted, altogether covering the perforation, forming a blunt angle, without any notch with the peristome, which is blunt and slightly expanded. Length 9, breadth  $5\frac{1}{2}$  mill.

*Pupina lubrica*, Sow. in *Proc. Z. S.* 1841, p. 102; *Thes.* n. 3, p. 18; t. 4, f. 12, 13; *Conch. Mon.* ed. ii. p. 90, f. 528, *Reeve. Conch. Syst.* t. 181, f. 9, 10

Smaller; uniformly yellow, or with a white band along the suture; height 6, greatest breadth  $8\frac{1}{2}$ , least br. 7 mill.

*Hab.* The Philippine Islands, Luzon, Mindanao, Zebu (H. Cuming).

(1573) *Helicina sublaevigata*.

Shell conoidally-depressed, rather solid, nearly smooth, slightly shining, uniformly reddish, or whitish, with a violaceous band beneath; spire shortly conoidal, with the apex rather blunt; whorls 5, scarcely convex, last broader, indistinctly angular on the periphery; aperture diagonal, rather semioval; columella short, simple, dilated backwards into a rather thick, circumscript callus; peristome simple, shortly expanded, with the basal margin nearly rectilinear, somewhat toothed at its junction with the columella. Operculum thin, horny. Height 5, greatest breadth 8, least br.  $6\frac{1}{2}$  mill.

*Helicina sublaevigata*, *Pfr. in. Proc. Z. S.* 1852; *Pneum. Mon.* p. 384.

*Hab.* The New Hebrides Islands.

(1574) *Helicina lutea*.

Shell orbiculate, convex, solid, thick, minutely striated above, gold-yellow; spire somewhat elevated, last whorls globose, slightly keeled on the periphery; aperture oblique, semicircular, shining and white within; columella white, sinuate; peristome simple, free. Height 3, breadth 5". (Less.)

*Helicina lutea*, Less. *Voy. Coquille*, p. 350, t. 13, f. 10; *Pfr. Pneum. Mon.* p. 387.

*Hab.* Port Dorey, New Guinea.

(1575) *Helicina Lindeni*.

Shell globose-conic, rather thin, very minutely striated and punctured, rather diaphanous, pale

## MOLLUSCA.

yellow or flesh-coloured; spire conic, rather pointed; whorls 6, scarcely convex, last inflated; obsolete angulated, not descending anteriorly; aperture somewhat oblique, semioval, higher than broad; columella slightly arcuate, terminating outward in a small tooth, dilated backwards into a small, thin callus; peristome narrowly expanded and somewhat reflected. Height  $8\frac{1}{2}$ , greatest breadth  $11\frac{1}{2}$ , least br. 10 mill.

*Helicina Lindeni*, *Pfr. in Proc. Z. S.* 1848, p. 123; *Ic.* n. 67, p. 52, t. 8, f. 22, 23; *Pneum. Mon.* p. 388.

*Hab.* Tapinapa, Mexico (Linden).

(1576) *Helicina agglutinans*.

Shell depressed-conic, rather thin, closely striated, yellow; spire broadly conic, pointed; whorls 5, rather flat, last keeled, scarcely descending anteriorly, flattened beneath; aperture very oblique, rather quadrangular; columella short, slightly holed, terminating outward angularly, dilated into a thin callus; peristome thin, with the upper margin scarcely expanded, basal margin narrow reflected; keel of young specimens winged with agglutinated decomposed particles of rocks. Operculum shelly, trapezoidally semioval. Height  $9\frac{1}{2}$ , greatest breadth 17, least br. 15 mill.

*Helicina agglutinans*, Sow. in *Proc. Z. S.* 1842, p. 7; *Thes.* n. 52, p. 11, t. 2, f. 8385; *Reeve. Conch. Syst.* ii. t. 186, f. 11, 12; *Pfr. Ic.* n. 75, p. 56, t. 2, f. 16-18; *Pneum. Mon.* p. 394.

*Hab.* The Philippine Islands of Guimaras, Bohol Pany (H. Cuming).

(1577) *Helicina pallida*.

Shell lenticular, rather solid, yellowish-gray, striated inequally, covered with a very thin periostraca; spire depressed; whorls 5, keeled, flattened; aperture semilunate, callus near the columella; labrum moderately reflected. Height  $\frac{3}{8}$ , breadth  $\frac{1}{10}$  inch. (Gould)

*Helicina pallida*, Gould, in *Proc. Bost. Soc.* 1847, p. 202; *Exped. Shells*, p. 37, ed. 1851, p. 96, f. 113; *Pfr. Pneum. Mon.* p. 296.

*Hab.* Feejee Islands.

(1578) *Helicina Lazarus*.

Shell depressed-conic, rather solid, coarsely striated and granulated, opaque, lemon-yellow; spire elevated, rather pointed; whorls  $5\frac{1}{2}$ , nearly flat, last keeled, equally moderately convex on both sides, scarcely descending anteriorly; aperture very oblique, almost triangular; columella extremely short, angularly terminating outward, sending backwards an arcuated line, which surrounds the thin basal callus; peristome simple, thin, scarcely expanded. Height 5, greatest breadth  $9\frac{3}{4}$ , least br.  $8\frac{1}{2}$  mill.

*Helicina Lazarus*, Sow. in *Proc. Z. S.* 1842, p. 7; *Thes.* n. 53, p. 11, t. 2, f. 91; *Pfr. Ic.* n. 78, p. 53, t. 7, f. 18, 19; *Pneum. Mon.* p. 396.

## MOLLUSCA.

*Hab.* The island of Luzon (H. Cuming)

(1579) *Helicina trochiformis*.

Shell, trochiform, soiled, faintly striated obliquely, opaque, pale straw-yellow; spire conic, pointed; whorls  $4\frac{1}{2}$ , flat, sharply and somewhat prominently keeled, last nearly flat beneath, descending anteriorly; aperture very oblique, nearly triangular; columella short, simple; peristome thin, with both margins expanded, scarcely angulated on the right side. Height 5, greatest breadth 8, least br. 7 mill.

*Helicina trochiformis*, Sow. in *Proc. Z. S.* 1842, p. 7; *Thes.* n. 49, p. 10, t. 2, f. 90; *Pfr. Ic.* n. 79, p. 59, t. 2, f. 12, 13; *Pneum. Mon.* p. 397.

*Hab.* The Philippine island of Negros (H. Cuming).

(1580) *Helicina tæniata*.

Shell nearly discoidal, faintly striated, yellowish-white, with a single red band; spire slightly raised, conoidal; whorls  $4\frac{1}{2}$ , last very large, strongly keeled, very convex beneath; aperture semilunate rather ovate; peristome simple, white, very, slightly reflexed; columella depressed, terminating in a small tooth. Breadth  $4\frac{1}{2}$ . (Quoy)

*Helicina tæniata*, Quoy & Gaim. *Voy. Astrol. Zool.* ii. p. 194, t. 12, f. 6-10; *Desh. in Lam. Hist.* viii. p. 159, n. 7; Sow. *Thes.* t. 2, f. 49, 51; *Pfr. Ic.* n. 85a, p. 63 (i. 19), t. A. f. 14 (from Quoy); *Pneum. Mon.* p. 398.

Smaller; rather globular, with two or three red bands (Quoy & Gaim. t. 11, f. 34-38).

*Hab.* The island of Vanikoro, the variety from Tonga.

(1581) *Helicina Stanleyi*.

Shell lenticular, convex above and beneath, orbicular, sharply keeled, fuscous-flesh-coloured, striated spirally; spire blunt; whorls  $4\frac{1}{2}$ , moderately convex, last imperforated beneath, smooth and white on the centre; aperture obliquely sub-lunate, angulated; peristome simple, thin. Height 5, greatest breadth  $6\frac{1}{2}$ , least br. 6 mill. (Forb.)

*Helicina Stanleyi*, Forbes, in *Voy. Rattlesnake*, *App.* p. 381, t. 3, f. 4; *Pfr. Pneum. Mon.* p. 401.

*Hab.* Duchateau Isles, Louisiade Archipelago (Macgillivray).

(1582) *Helicina Nicobarica*.

Shell lenticular, rather thin, smooth, slightly shining, whitish or horn-coloured, painted usually with one or two narrow red bands; spire short, blunt; whorls 4, nearly flat, enlarging gradually, last sharply keeled, more convex beneath, marked sometimes with indistinct raised spiral lines; aperture somewhat oblique, obtusely triangular; columella short, with an indistinct knot; peristome sharp, expanded very narrowly; basal callus shining, surrounded with a whitish line. Operculum thin, flesh-coloured. Height  $3\frac{1}{2}$ , greatest breadth  $5\frac{1}{2}$ , least br. 5 mill.

*Helicina Nicobarica*, Philippi in *Z. f. M.* 1847, p. 149; *Pfr. Ic.* n. 85, p. 52, t. 2, f. 19-21; *Pneum. Mon.* p. 402.

## MOLLUSCA.

*Hab.* The Nicobar Islands (Th. Philippi).

*Stoastoma. rec.* 19 sp.

(1583) *Stoastoma succineum*.

Shell umbilicate, globose-conic, thin, smooth, pellucid, amber-coloured; spire conic, rather pointed; whorls 6, moderately convex, the last one excavate beneath; umbilicus narrow, open; aperture somewhat oblique, semioval; peristome simple, sharp, furnished at the base of the columellar margin with a small callus tongue, which is horizontally produced into the umbilical keel. Operculum typical. Height 4, greatest breadth  $4\frac{1}{2}$ , least br.  $3\frac{1}{4}$  mill.

*Cyclostoma succineum*, Sow. in *Proc. Z. S.* 1832, p. 32 (*Mull. Synops.* p. 87); *Thes.* n. 51, p. 108, t. 23, f. 18, 19; *Pfr. Ic.* n. 15, p. 24, t. 3, f. 12-14.

Genera, *Avicula*, *rec.* 25 sp. *fossil* 300 sp.

*Sub-genera.* *Meleagrina*. Pearl-oyster, *rec.* 3 varieties.

In several of the shallow bays of Singapore an abundance of a small species of *Meleagrina* or Mother of Pearl Oyster, few of the shells are larger than the palm of the hand, and of a dark slate colour. Those accustomed to trade in Mother of Pearl, that this kind never attains a large size. Dr. Traill was at first inclined to doubt the accuracy of the statement, as I do not find more than two described species, namely, the *M. margaritifera*, and *M. albina* which is also to be found here. What leads to the supposition of its being a distinct species is that the large kind has never been picked up here.

(1595) *Sphaerium Indicum.*

S. testa ovato-rhomboidea, tumidula, sub-  
aequilaterali, tenui, pellucida, albo-grisea, la-  
tere antico late rotundato, postico obtuse trun-  
cato; umbonibus tumidis, parum prominentibus;  
cardine obsolete bidentato, dentibus laterali-  
bus candidis, antico majore trigono, acuto, postico  
paulo brevior; valvis sublente tenuissime striatis.

*Sphaerium Indicum, Desh. Proc. Zool. Soc.*  
1854.

*Hab.* In fluviis Indiae.

(1596) *Sphaerium Capense.*

S. testa ovato-orbiculari, tumida, subglobosa,  
tenui, cornea, aequilaterali, transversim tenuis-  
sime striata; extremitatibus rotundatis, postice  
obtusior; apicibus marginibusque obtusis;  
dentibus cardinalibus minimis, lateralibus val-  
vulae dextrae prominentibus, acutis.

*Cyclas Capensis, Krauss, Sudaf. Moll. p. 7.*  
No. 1. pl. 1. f. 5.

*Hab.* Caput Bonae Spei.

*Sub-genus. Pisidium, rec.*

*Cyrena malaccensis. Malacca.*

*Cyrena. Moulmein.*

*Cyrena. Gurseppa Village on the Honawer River*  
*? Cyrenoides. Syn. Cyrenella, rec.* 1. sp.

(1597) *Cyrena triangularis.*

C. testa trigona, solidiuscula, epidermide fus-  
co-virescente, transversim striata, striis marginali-  
bus lateralibusque eminentioribus, sulco ab um-  
bone ad marginem posteriorem leviter impressa;  
margine antico descendente, vix excavato, angu-  
lo anteriore rotundato; margine superiore subro-  
tundato, postico fere biangulato; valvis intus  
lacteis, margine continuo nitentior; dentibus  
cardinalibus in utraque valva tribus, duobus  
bifidis; dentibus lateralibus brevibus, tenuissime  
rugosis haud stratis.

*Cyrena triangularis, Metcalfe. Proc. Zool. Soc.*  
1851, p. 74. no. 36.

*Hab.* Borneo.

(1598) *Cyrena turgida*.

C. testa trigona, inflata, parte antica turgida, rugoso, inaequilaterali, transversim rugata; valvulis crassis, natibus, elevatis, recurvis; dentibus cardinalibus sub-bifidis; dente anteriore laterali brevi et elevato, posteriore longo et laminato; margarita alba.

*Cyrena turgida*, *Lea. Trans. of Amer. Phil. Soc.* v. 109. pl. 18. f. 53, *Observ. on the Genus Unio*, i. 221. pl. 18. f. 53.

*Hanley, Descr. Cat.* i. 93; in *Wood, Ind. Test. Suppl.* 2, pl. 14. f. 50.

*Hab.* In fluviis Indiæ.

(1599) *Cyrena Sumatrensis*.

C. testa ovali, gibbosa, crassa, intus alba aut flavescens, extus fusco-virescente; dentibus cardinalibus tribus, duobus majoribus, angulatis, sub-bifidis, dentibus lateralibus brevibus, tenuissimis sine rugosis.

*Cyrena Sumatrensis*, *Sow. Gen. of Shells*, f. 1-4.

*Desh. Lamk. An. s. Vert.* ed. 2. vi. 277. no. 15.

*Reeve. Conch. Syst.* pl. 63

*Hanley, Descr. Cat.* p. 94; in *Wood, Ind. Test. Sup.* 2. pl. 15, f. 1.

*Hab.* In rivulis insulæ Sumatrensis.

(1600) *Cyrena Bengalensis*.

C. testa subcordata, trigona, inaequilaterali, tumidiuscula, crassa, solida, alba sub epidermide squalide fuscescenti, transversim irregulariter striata; latere antico valde declivi, planulato, posteriore dorsali parum convexo; margine inferiori vix arcuato; umbonibus erosione oblique incurvatis parum prominentibus; valvis intus albis, cardine incrassato oblique tridentato; dentibus subparallelis sensim crescentibus, duobus in valva dextrabifidis uno mediano in valva sinistra; antico minore, dentibus lateralibus maximis, brevibus, simplicibus; impressione pallii prope marginem inferiorem descendente; nymphis latis, depressis; ligamento angusto, brevi, partim immerso.

*Cyrena Bengalensis*, *Desh. Lam. An. s. Vert.* ed. 2. vi. 276. no. 10.

*Deless. Rec. de Coq.* pl. 7. f. 6. a.d.

*Hanley, Descr. Cat.* p. 91; in *Wood, Ind. Test. Suppl.* 2. pl. 13. f. 14.

*Hab.* In rivulis Bengalensibus.

(1601) *Cyrena Buschii*.

C. testa trigono-orbiculari, inaequilaterali, alba, incrassata, solida, tumidiuscula; epidermide olivacea-viridi vel castanea, regulariter concentricè lamellata; latere antico brevi, obtuso, declivi, rectilineo, planiusculo; postico convexiusculo, ad extremitatem obtuso; inferiore parum arcuato; umbonibus oblique prominulis, sæpius integris, cardine angusto, dentibus cardinalibus tribus, inaequalibus sensim crescentibus, duobus posticis valvæ dextræ anterioribus, valvæ sinistræ bifidis, dentibus lateralibus brevibus, antico cardine approximato.

*Cyrena Buschii*, *Phil. Abbid. Conch.* p. 8. no. 2 pl. 2. f. 2.

*Hab.* China.

(1602) *Cyrena expansa*.

C. testa crassiuscula, subinflata, inaequilaterali, rotundato-trigona, lineis transversis æquidistantibus, antice punctatis, postice crispulatis ornata nitida, extus viridi-lutea, intus tota alba; margine cardinali, brevi, anteriori et inferiori rotundatis; posteriori subexpanso, infra angulato; dentibus cardinalibus duobus bifidis, tertio simplici, in valva dextra anteriori, in sinistra posteriori; dente laterali antico subapproximato, posteriori subremoto.

*Cyrena expansa*, *Mousson, Mall. Javo* p. 89. No. 6. pl. 14.

*Hab.* Insula Javanica (*Mousson*).

(1603) *Cyrena fallax*.

C. testa ovato-trigona, plus minusve tumida, crassa, solida, in medio ventricosa, epidermide squalide, fuscescente, ferruginea, in junioribus flavescens vestita, transversim irregulariter striata; latere antico brevius, superne fere rectilineo, declivi rotundato, margine postico, superiore recto, declivi; extremitate postica sensim attenuata, breviter truncata; area plana, lævigata, angulo obtusissimo circumscripta; cardine satis latodentibus tribus inaequalibus in valva dextra crassioribus majoribus bilobatis; dente laterali antico compresso brevi, postico longiore.

*Cyrena fallax*, *Desh. Proc. Zool. Soc.* 1854.

*Hab.* Insulæ Philippinenses; Australia (*Cuming*). Coll. *Cuming*.

(1604) *Cyrena inquinata*.

C. testa orbiculato-trigona, turgida, inflata, subcordiformi, inaequilaterali, epidermide squalide fusca, fuliginosa dense irregulariter, lamellosa vestita; umbonibus tumidis profunde erosione; margine superiore antico declivi, rectilineo, postico convexiusculo, inferiore subsemicirculari; valvis solidiusculis intus albis; cardine angusto, arcuato, tridentato; dentibus inaequalibus, brevibus, obliquis, parallelis, angustis, parum prominentibus, duobus bifidis; dentibus lateralibus minimis, brevibus antico prominentiore; ligamento brevi, partim infosso; impressione pallii prope marginem decurrente.

*Cyrena inquinata*, *Desh. Proc. Zool. Soc.* 1854.

*Hab.* In fluviis Chinensibus.

(1605) *Cyrena similis*.

C. testa ovato trigona, oblonga, inaequilaterali, in medio tumida transversim distanter striata, epidermide fuscescente, ferruginea nitente vestita; umbonibus minimis decorticatis; latere antico brevi, rotundato, obtuso, latere postico superne convexiusculo, declivi, sensim attenuato, extremitate breviter subtruncato; dentibus tribus, primariis duobus subæqualibus apice inaequaliter bifidis dentibus lateralibus minimis, antico valvæ sinistræ conico, depressiusculo, postico longiore

*Cyrena oblonga*, *Desh. Proc. Zool. Soc.* 1854.

*Hab.* Manila. Coll. Cuming.

(1606) *Cyrena oviformis*

C. testa ovato transversa, crassa, solida turgida, inaequilaterali, transversim irregulariter incrementis striata; area lunulaque laevigatis, epidermide tenui, brunnea vel flavesciente vestita antice brevi declivi, obtusa, postice magis attenuata; latere superior postico convexiusculo umbonibus brevibus, depressis, apice acuminatis. saepius erosis; ligamento angusto, elongato, vix immerso; valvis profundis, intus albis; cardine angusto, arcuato, inaequaliter tridentato; dentibus divaricatis, duobus in utraque valva inaequaliter apice bilobatis dente laterali antico conico, crasso, prominenti compresso dente postico longiore, angustiore.

*Cyrena oviformis*, *Desh. Proc. Zool. Soc.* 1854.

*Hab.* Insula Basilan Philippinarum; Portus Essingtonensis. Coll. Cuming.

(1607) *Cyrena ventricosa*.

C. testa ovato-transversa, subtrigona, inaequilaterali, in senioribus, crassa solida, ponderosa, in medio turgida, epidermide squalide fusciscente aut rubiginosa, tenui, inferne posticeque breviter lamellosa et atrata, vestita intus candidissima. antice superne arcuato-declivi, obtusa postice sensim attenuata, truncata; margine superiore dorsali rectilineo, declivi; umbonibus parvis, parum obliquis; cardine angusto, tridentato, dentibus inaequalibus majoribus bifidis subparallelis: dentibus lateralibus crassis, compressiusculis-postico paulo longiore; ligamento angusto, partim immerso; area posticali planata.

*Cyrena ventricosa*, *Desh. Proc. Zool. Soc.* 1854.

*Hab.* Insulae Philippinenses; Australia. Coll. Cuming.

(1608) *Cyrena Galathea*.

C. testa cordato-trigona, inaequilaterali turgida concentricè striata, postice, longiore, truncata, antice, et inferne angulata; umbonibus distantibus, prominentibus; lunula rhomboidali, medio carinata; area lanceolata, convexa; ligamento tumido, longiore, valvis intus albis, cardine forniceque flavescens; epidermide nigrescente, antice obsolete radiata; dentibus lateralibus brevibus, antico conico intraute, postico oblongo.

*Cyrena Galathea*. *Morch. Cat. Conch. Kierulff*, p. 32. t. 2. *Zeitsch. für Malac.* No. 8. p. 128.

*Hab.* In insula Nicobar, fluv. Galathea.

(1609) *Cyrena cyprinoides*.

C. testa magna, turgida, cordata, inaequilaterali, transversim striata; epidermide viridi, antice posticeque fusciscente; cardine angusto; dentibus lateralibus brevibus.

*Cyrena cyprinoides*. *Quoy. & Gaim. Voy. del Astrol. Moll.* pl. 82. f. 1. 2. 3. (non Gray).

*Hanley. Descr. Cat.* p. 93; *Wood. Ind. Test. Suppl.* 2. pl. 14. f. 54.

*Hab.* In aquis paludosis. stagnantibus, Novae Guinea (*Quoy*).

(1610) *Cyrena divaricata*.

C. testa ovato-subcirculari, inaequilaterali, tumida, crassa, solida, epidermide fusco-nigrescente vestita, transversim, inaequaliter obsolete striata, rugis undulatis, irregularibus in latere postico divergentibus; umbonibus obliquis, profunde erosis; latere antico brevior, superne recto, declivi, in medio attenuato, sub-angulato, latere, postico lato, dilatato obtuse sub, truncato lamina cardinali lata plana; dentibus primariis tribus inaequalibus, angustissimis, in valva sinistra duobus satis valde pediculatis, in valva dextra profunde canaliculatis; dentibus lateralibus minimis, antico conico, acuto, postico oblongo, angusto.

*Cyrena divaricata*, *Desh. Proc. Zool. Soc.* 1854.

*Hab.* Nova Guinea.

(1611) *Cyrena zeylanica*

C. testa ovato-transversa, inaequilaterali, tumida, epidermide transversim striata olivaceo-viridi vestita; antice posticeque aequaliter declivi extremitatibus rotundata, inferne convexiuscula; umbonibus parum obliquis, erosis; intus alba; cardine angusto, tridentato, dentibus inaequalibus subparallelis, mediano et posticali valvae dextrae, antico et mediano valvae sinistrae apice bifidis; dentibus lateralibus brevibus, simplicibus, a cardine parum remotis.

C. testa ovato-trigona, æquilaterali subcordiformi, transversim dense striato-sulcata; striis regularibus, antice posticeque evanescentibus; epidermide nitente, nigro-virescenti vestita, in latere postico tenuissime striato-lamellosa, intus violacea; umbonibus angustis, prominentibus, antice obliquatis; latere antico atque postico

## MOLLUSCA.

aequaliter convexiusculis, declivibus, obtusis; cardine angusto, dentibus tribus primariis inaequalibus brevibus simplicibus, antico valvæ dextræ dente laterali adnato; dentibus lateralibus aequalibus, longis extremitate inferiore leviter arcuatis, crenulato-striatis.

*Corbicula ambigua*, *Desh. Proc. Zool. Soc.* 1854.

*Hab.* Flumen Euphrates.

d. *Species Indicae.*

(1621) *Corbicula occidens*.

C. testa ovato-transversa, æquilaterali, tumida, tenui, transversim regulariter lirato-sulcata; epidermide flavescens-viridi vestita, ad umbones atro-violascente vel breviter albo radiata; umbonibus tumidis, brevibus, lævigatis; lunula ovato-lanceolata, pallida, lævigata; valvis intus profunde fusco-violascentibus; cardine angusto, inaequaliter tridentato; dentibus lateralibus brevibus angustis albis tenue striatis.

*Corbicula occidens*, *Bens. Asiat. Journ.* 1824?

*Hab.* India; loco Sikkim dicto, Moredabad, Bengal, Coll. Cuming.

(1622) *Corbicula Bensoni*.

C. testa ovato-transversa, subtrigona, æquilaterali, lævigata, nitida, depressiuscula, extremitatibus obtusa, utroque latere aequaliter declivi; epidermide tenui, intente, virescente vel flavescens induta, aliquantisper lineis interruptis fuscis radiata, alba vel pallide violascente; cardine angusto, tridentato, dentibus inaequalibus valde divaricatis dentibus lateralibus prælongis angustissimis, tenuissime striato crenatis, antico paulo longiore.

*Corbicula Bensoni*, *Desh. Proc. Zool. Soc.* 1854.

*Hab.* In rivulis Bengalensibus (*Benson*). Coll. Cuming.

(1623) *Corbicula Bengalensis*.

C. testa ovato-subtrigona, depressiuscula, tenui, subæquilaterali, obsolete transversim striata, striis regularibus distantibus; epidermide flavescens nitidissima, intus alba, in medio macula rubescens notata; umbonibus minimis acutis; cardine angusto tridentato, altero bidentato; dentibus lateralibus angustissimis, argute striatis.

*Corbicula Bengalensis*, *Desh. Proc. Zool. Soc.* 1854.

*Hab.* In rivulis Bengalensibus, Coll. Cuming.

(1624) *Corbicula striatella*.

C. testa ovato-transversa, depressiuscula, subæquilaterali, extremitatibus aequaliter obtusa, transversim regulariter lirata, liris ad latus posticum evanescentibus; epidermide pallide viridescens, nitente vestita; intus atro-violacea; umbonibus brevibus, atro-violascentibus, pallidioribus biradiatis; cardine angusto, tridentato; dentibus inaequalibus, divaricatis, postico longiore et angustiore, dentibus lateralibus elongatis, angustis, subæqualibus, arcuatis, tenuissime striatis.

*Corbicula striatella*, *Desh. Proc. Zool. Soc.* 1854.

## MOLLUSCA.

*Hab.* Pondicherry. Coll. Cuming.

(1625) *Corbicula trigona*.

C. testa trigona, æquilaterali, compressiuscula, antice paulo latiore et obtusiore, utroque latere aequaliter declivi, transversim tenue et regulariter striata; epidermide viridi, nitente induta, intus pallide violacea; umbonibus minimis, brevibus, acutis; lunula ovata, angulo obsoleto circumscripta, pallida, lævigata; cardine angusto, altero bidentato altero tridentato; dentibus lateralibus aequalibus, tenuissime striatis antico leviter arcuato.

*Corbicula trigona*, *Desh. Proc. Zool. Soc.* 1854.

*Hab.* Pondicherry, Coll. Cuming.

(1626) *Corbicula Cashmiriensis*.

C. testa ovato-transversa, subtrigona, æquilaterali, tumidula, transversim tenue et regulariter striata, striis postice evanescentibus; epidermide nitida, atro-virescente, in latere postico tenuissime striato vestita; umbonibus tumidis, prominentibus, profunde erosis, violaceis; cardine angusto, in valva dextra bidentato, in altera tridentato, valvulæ dextræ dente antico laterali adnato; dentibus primariis divergentibus, simplicibus, lateralibus, longis, angustis, antico longiore cardine proximo; valvis intus violaceis, impressione pallii margine valve remoto.

*Corbicula Cashmiriensis*, *Desh. Proc. Zool. Soc.* 1854.

*Hab.* Cashmere, Coll. Cuming.

(1627) *Corbicula Woodiana*.

C. testa subtrigona, subinflata, micante, subæquilaterali, transversim rugata; valvulis crassis; natibus magnis et rotundatis; dentibus cardinalibus subbifidis, lateralibus longis, serratis rectisque; margarita alba.

*Cyrena Woodiana*, *Lea. Trans. Amer. Phil. Soc.* v. 110 pl. 18, f. 55; *Observ. on the Genus Unio.* i. 222, pl. 18, f. 55.

*Wood Ind. Test. Suppl.* 2. pl. 14, f. 58.

*Hab.* In rivulis Chinensibus prope Canton.

(1628) *Corbicula grandis*.

C. testa orbiculato-trigona, solida, tumidula, inæquilaterali, transversim irregulariter rugosa, antice sulcis magis regularibus exarata; latere antico brevior, late arcuato, postico magis attenuato; epidermide nitidissima nigrescente vestita, ad margines flavescens, postice squamosa; valvis intus pallide flavis; cardine incrassato, tridentato, dentibus approximatis, lateralibus brevibus, crassis, irregulariter striato-denticulatis.

*Corbicula grandis*, *Desh. Proc. Zool. Soc.* 1854.

*Hab.* China? Coll. Cuming.

(1629) *Corbicula similis*.

C. testa trigona, paululum latiore quam alta, depressiuscula, subæquilaterali, transversim tenue sulcata, postice sulcis evanescentibus; latere antico rotundato, obtuso, postico productiore

# MOLLUSCA.

cuneiformi, angulato; umbonibus prominentibus, recurvis, oppositis, decorticatis; ligamento brevi, angusto, partim immerso; epidermide viridi-suscescente ad margines glaucescente; valvis intus albis, ad margines lutescentibus, cardine tridentato, nymphis basi irregulariter granoso-rugosis; dentibus lateralibus prælongis, angustis, transversim late profundeque sulcatis.

Venus similis, *Gray in Wood, Ind. Test. Supp.* 1. pl. 2. f. 5.

Cyrena similis, *Gray, in Griff. Anim. Kingd.* pl. 20. f. 2.

*Hab.* China?

## (1630) *Corbicula Largillierti*.

C. testa rotundato-trigona, subæquilaterali, compressiuscula, postice angustiore, subangulata; striis transversis confertissimis; epidermide olivacea, apicibus et pagina interna violaceis; dentibus lateralibus elongatis, striatis.

Cyrena Largillierti, *Phil. Abbild. Conch.* pl. 1. f. 1.

*Menke, Zeits. für Malak.* 1844. p. 163.

*Hab.* China.

## (1631) *Corbicula recurvata*.

C. testa trigona, brevi, alta, crassa, cordiformi, æquilaterali; lateribus subæqualibus, fere rectilineis, latere antico obtuso, postico angulato, margine inferiore vix arcuato; umbonibus angustis, prominentibus, oppositis, sæpius erosis; facies externa regulariter transversim sulcata, epidermide flavesciente fusco zonato; valvis intus albis; cardine bidentato, dentibus lateralibus rectis, longissimis, simplicibus.

Cyrena recurvata, *Eydoux, Moll. du Voy. de la Favorite, Mag. de Zool.* p. 11. pl. 119. f. 2.

*Hab.* In fluviis Chinæ, atque lacu et rivis prope Manillam.

## (1632) *Corbicula fluminea*.

C. testa triangulari, gibba, opaca, antice et postice versus cardinem fere æqualis, epidermide viridi vestita, costis latis, transversim quasi circulis doliaribus circumdata intus albida, *semicirculo nigro notata*; dentibus cardinalibus et fossulis uti in præcedente (fluviatilis, *Muller*).

*Tellina fluminea, Mull. Verm.* ii. 206.

*Gmel.* p. 3243. no. 80.

*Cyclas fluminea, Blainv. D. S. N.* xii. 280.

*Venus fluminea, Chemn. Conch.* vi. 320. pl. 30 f. 322, 323, an eadem species?

*Schrot. Einl.* iii. 159. no. 13.

*Wood. Ind. Test.* pl. 8. f. 114.

*Tellina fluviatilis, Schrot. Flussconch.* p. 193. pl. 4. f. 2. a. b.

*Cyrena fluminea, Lamk. An. s. Vert.* v. 553. no. 5.

*Hanley, Descr. Cat.* p. 92.

*Phil. Abbild. Conch.* p. 2. no. 3. pl. 1. f. 3, an eadem species?

*Mousson, Moll. de Java,* p. 87. no. 2. pl. 15. f. 3.

# MOLLUSCA.

*Hab.* In arena fluviatili Chinæ (*Muller*); Java (*Mousson*); Manila (*Cuming*).

## (1633) *Corbicula fluviatilis*.

C. testa triangulari, transversim rugosa; testa latior et tenuior, proxima præcedenti (fluminalis), fusco-virens, in cardine antice et postice æqualis latitudinis; lineis elevatis cincta (*Mull.*)

*Tellina fluviatilis, Mull. Hist. Verm.* ii. 206.

*Gmel.* p. 3243. no. 81.

*Cyclas fluviatilis, Blainv. D. S. N.* xii. 280.

*Venus fluviatilis, Chemn. Conch.* vi. 320. pl. 30. f. 321.

*Wood, Ind. Test.* pl. 8. f. 115.

*Venus, Schrot. Einl.* iii. 158. no. 12.

*Cyrena fuscata, Lamk. An. s. Vert.* v. 552. no. 4. exclus. var.

*Cyrena fluviatilis, Phil. Abbild. Conch.* p. 3. n. 5. pl. 1. f. 5?

*Cyrena Manilensis, Phil. Zeits. für Malac.* 1841, p. 163.

*Hab.* In flumine emporium Canton, Chinæ præterlabente (*Muller*).

## (1634) *Corbicula orientalis*.

C. testa rotundato-ovata, subtrigona, subæquilaterali, solida; apicibus erosis, obtusis; striis transversis regularibus remotis; epidermide olivaceo-atra; dentibus cardinalibus duobus in valvula dextra; dentibus lateralibus elongatis striatis.

*Cyrena orientalis, Lamk. An. s. Vert.* v. 552. no. 2, exclus. var.

*Desh. in Lamk. ed. 2.* vi. 273, no. 2.

*Anton, Vert. der Conch.* p. 13. no. 496, excl. syn.

*Phil. Abbild. Conch.* p. 1. no. 2. pl. 1. f. 2.

*Hab.* In China; in fluvio emporium Canton præterlabente, frequentissima; pro calce uritur (*Phil.*)

## (1635) *Corbicula nitens*.

C. testa trigona, inæquilaterali, tenui, tenuissime et confertissime transversim striata, olivaceo-flava; extremitate postica subrostrata fusca; dentibus lateralibus elongatis striatis.

*Cyrena nitens, Philippi in Menke, Zeits. für Malac.* 1844, p. 153;

*Abbild. Conch.* p. 76. pl. 1. f. 4.

*Hab.* China.

## (1636) *Corbicula compressa*.

C. testa ovato-trigona, transversa, subæquilaterali, fusca, transversim tenue et regulariter sulcata; antice brevior, obtusa, postice obscure truncata; sulcis ad latus posticum evanidis; umbonibus obtusis, brevissimis decorticatis; valvis tenuibus, intus atro-violaceis; cardine angusto, sæpius candido, tridentato; dentibus lateralibus angustis, acutis tenuissime striatis.

*Cyrena compressa, Mousson. MSS. fide Morelet.*

*Hab.* In rivulis insulæ Javanæ.

## (1637) *Corbicula Moussoni*.

C. testa ovato-transversa, convexiuscula, inæquilaterali, transversim striato-sulcata, striis remotis, æqualibus, fusco-nigra; umbonibus inflatis, obtusis, erosis; cardine angusto; dentibus cardinalibus tribus, dente mediano crassiore, postico angusto obsoleto; dentibus lateralibus angustis, brevioribus tenuissime striatis; valvis intus violaceis, ad dentes laterales fusco-violaceis.

Cyrena orientalis, var. Javanica, *Mousson, Moll. terr. et fluv. de Java*, p. 85. pl. 15. f. 2.

*Hab.* Tikojia in insula Javanica.

(1638) *Corbicula pulchella*.

C. testa ovato-orbiculari, vix trigona, subæquilaterali, lenticulari, apicibus perspicuis, transversim tenuiter sulcata, extus olivacea, intus pallide luteo-alba; margine cardinali brevi, anteriori angulo rotundato inferiori juncto; posteriori subtruncato; dentibus lateralibus valde elongatis, tenuissimis, minute serrulatis; dentibus cardinalibus minutis, intraque valva, angulo cardinali 120.

Cyrena pulchella, *Mousson, Moll. Java*, p. 88. no. 3. pl. 15. f. 4.

*Hab.* Insulam Javanicam prope Tjikoya.

(1639) *Corbicula rivalis*.

C. testa trigona orbiculari, æquilaterali, compressa, satis tenui, olivacea, sulcis concentricis confertis cincta; umbonibus acutiusculis, parum prominentibus; dentibus lateralibus elongatis, serrulatis, anticis subæqualibus; pagina interna omnino violacea.

Cyrena rivalis, *Von dem Busch in Pill. Abbild. Conch.* iii. 110. no. 5. pl. 3. f. 5.

*Hab.* Java.

(1640) *Corbicula Cumingii*.

C. testa ovata, subtrigona, inæquilaterali, tenui, turgida, subcordiformi; epidermide nitente viridescente vestita, transversim regulariter-sulcata, sulcis distantibus postice evanidis; umbonibus tumidis, prominentibus, lævigatis, atro-violaceis, sæpius, integris, oppositis; cardine angusto, inæqualiter tridentato, dentibus divergentibus; nymphis basi granoso-corrugatis; dentibus lateralibus angustis elongatis, æqualibus, antico in medio prominentiore.

*Corbicula Cumingii*, *Desh. Proc. Zool. Soc.* 1854.

Var. Testa globulosa, ventricosiore.

*Hab.* Insula Luzon Philippinarum, (*Cuming*); India, Bareilly loco dicto, (*Benson*).

(1641) *Corbicula Malaccensis*.

C. testa ovato-transversa, subtrigona, inæquilaterali, turgidula, solidula; epidermide glaucescente vestita, transversim regulariter et tenue sulcata, extremitatibus obtusa, latere antico longiore; cardine angusto, tridentato, altero bidentato; dentibus lateralibus angustis, tenuissime striatis, antico longiore, valvis intus albis vel pallide violaceo tinctis.

*Corbicula Malaccensis*, *Desh. Proc. Zool. Soc.* 1854.

*Hab.* In rivulis ad Malaccam affluentibus. Coll. *Cuming*.

(1642) *Corbicula tumida*.

C. testa regulariter ovato-transversa, tumida, tenui, subæquilaterali, postice paulo longiore, utraque extremitate æqualiter obtusa; epidermide viridi, nitente vestita, transversim sulcata, sulcis valde distantibus; umbonibus parvis, turgidulis, integris; cardine angustissimo, dentibus cardinalibus tribus angustis, inæqualibus, valde divergentibus lateralibus angustissimis, arcuatis, argute crenulato-striatis.

*Corbicula tumida*, *Desh. Proc. Zool. Soc.* 1854.

Var. Testa, juniore epidermide glaucescente, valvulis intus extusque fusco trimaculatis.

*Hab.* Borneo. Coll. *Cuming*, pro varietate.

(1643) *Batissa rotundata*.

B. testa rotundata, sublenticulari, subæquilaterali, transversim rugata; latere posteriori rugoso; valvulis crassis; natibus parvis, acutis, contiguis; dentibus cardinalibus subbifidis; lateralibus longis, minute serratis, rectisque; margarita alba et purpurea.

Cyrena rotundata, *Lea, Trans. of Amer. Phil. Soc.* v. 107. pl. 17. f. 51; *Observ. on the Genus Unio*, i. 319. pl. 17. f. 51.

*Hanley, Descr. Cat.* p. 93; in *Wood, Ind. Test. Suppl.* 2. pl. 14. f. 55.

*Hab.* Java; insulæ Philippinenses.

(1644) *Batissa eximia*.

B. testa ovato-orbiculari, crassiuscula, inæquilaterali, transversim striata, margine subrugosa, umbonibus tumidis, obliquis, haud erosis, plicis obsoletis rugulosis irregularibus ab iisdem ad latus posticum decurrentibus; epidermide atro-fusca marginem versus sublamellosa; intus alba, dentibus cardinalibus in utraque valva tribus, majoribus bifidis, lateralibus valvæ sinistrae haud crenulatis, antico valde crasso, brevi, cardine approximato, dente postico remoto, longiore, subcompresso, ligamento peculiari crasso, in dorso compresso et carinato.

Cyrena eximia, *Dunk. Zeitsch. für Malac.* 1852. p. 51. no. 4.

*Hab.* In flumine Progo, prope Mangelang, in insula Java.

(1645) *Batissa Keraudrenia*.

B. testa obovata, inæquilaterali, crassa, solida, compressiuscula, maxima latere antico brevi, rotundato, postico latiore, superne subdeclivi, angulum obtusum ad extremitatem ligamenti formante, margine ventrali convexiusculo; umbonibus recurvis, prominulis; obliquis, approximatis, sæpius integris aliquantisper erosis ligamento permagno, prominente cylindræo, postice subito truncato; epidermide crassa, atro-fuscescente vel olivacea valvis intus albis, ad margines inferne posticeque purpureo-violaceis; cardine incrassato dentibus cardinalibus inæqualibus, mediano valvæ dextræ majore, antico brevior, postico angustiore et longiore dentibus laterali-

## MOLLUSCA.

bus angustis, elongatis, superne transversim striatis, aliquantisper violaceo tinctis.

Cyrena Keraudrenia, *Lesson. Voy. de la Coq. Moll.* p. 429. pl. 11. f. 3 (1829).

Cyrena philippinarum, *Hanley, Proc. Zool. Soc.* 1844, p. 259; in *Wood. Ind. Test. Suppl.* 2 pl. 14. f. 60.

Var. Testa paulo depressiore, postice angulata.

Hab. Insula Waigiou dicta atque insulæ Philippinenses; fluviis insulæ Nicobaricæ.

(1646) *Batissa insignis*.

B. testa ovato-orbiculari, oblique inæquilaterali, tumida, tenui, intus violacea, epidermide nigro-virescente, nitido vestita, in latere antico late sulcata, sulcis remotis, ad lunulam sæpius inter se conjungentibus; umbonibus prominentibus erosis, antice inclinatis; cardine angusto, obliquo, inæqualiter tridentato; dentibus in valva sinistra angustioribus, mediano bifido, in dextra crassioribus simplicibus; dentibus lateralibus angustis, postico valvæ sinistræ laminato apice regulariter serrulato.

*Batissa insignis*, *Desh. Proc. Zool. Soc.* 1854.

Hab. Calamang, insula Luzon Philippinarum. Coll. Cuming.

(1647) *Batissa triquetra*.

B. testa trigona, obliqua, inæquilaterali, cuneiformi, lævigata, epidermide nigro vestita, depressiuscula; margine antico rectilineo postico valde convexo, dilatato, inferiore vix arcuato; umbonibus profunde erosis; lamina cardinali angusta, dentibus cardinalibus tribus inæqualibus, brevibus, subcanaliculatis; lateralibus elongatis, angustis, subæqualibus, antico cardine adnato, postico remoto; valvis tenuibus intus albis.

*Batissa triquetra*, *Desh. Proc. Zool. Soc.* 1854.

Hab. Insulæ Philippinensis; Australia. Coll. Cuming.

(1648) *Batissa producta*.

B. testa suborbiculari, valde obliqua, inæquilaterali, depressiuscula, crassa, solida, transversim late et obsolete plicata vel subundulata, epidermide polita, atro-virescente vestita, intus superne alba, postice inferneque violacea; umbonibus magnis, productis, antice obliquatis; cardine lato, crasso, valde obliquo, inæqualiter tridentato dentibus majoribus superne obsolete, canaliculatis, lateralibus validis, antico, crasso, obsolete rugoso vel striato, postico compressiore et paulo longiore, latere antico brevi rotundato, postico dilatato.

*Batissa producta*, *Desh. Proc. Zool. Soc.* 1854.

Hab. Insulæ Philippinenses. Coll. Cuming.

(1649) *Batissa Childrenæ*.

B. testa ovato-subrotunda, obliqua, inæquilaterali, depressiuscula, crassa, solida, postice ab umbonibus obscure subangulata, epidermide fusco-viridi nitente induta, intus alba, in fornice sæpius aurantio-purpurascens postice violacea; latere antico brevior, obtuso, transversim inæ-

## MOLLUSCA.

qualiter sulcato; sulcis in medio evanidis; latere postico latiore rugis irregularibus divergentibus notato, lamina cardinali lata, crassa, dentibus primariis tribus inæqualibus, in utraque valva medianis validioribus; dentibus lateralibus subæqualibus, antico basi lato.

*Cyrena Childrenæ*, *Gray. Ann. Phil.* 1825, p. 117.

Venns Childreni, *Gray in Wood, Ind. Suppl.* pl. 2 f. 13.

Var. Testa mimore paulo transversiore magis depressa.

Hab. Insulæ Philippinenses.

(1650) *Batissa lenticularis*.

B. testa orbiculari, tantum alta quam lata, æquilaterali, subsymmetrica, lenticulari, turgidula, epidermide nitidissima atro-virescente vestita, lineis longitudinalibus tenuissimis obsoletis irregulariter in medio radiata, intus albo-violacea; latere antico posticum æquante et æqualiter obtuso; cardine angusto, tridentato; dentibus majoribus superne canaliculatis, mediano valvæ dextræ majori; dentibus lateralibus subæqualibus, antico crassiore, tenue rugoso, postico laminato obsolete striato; umbonibus parvis, acutis, integris, oppositis.

*Batissa lenticularis*, *Desh. Proc. Zool. Soc.* 1854.

Hab. Insulæ Philippinenses (Cuming). Coll. Cuming.

(1651) *Batissa Jayensis*.

B. testa subrotunda, inæquilateralis, antice rugosa; valvulis crassis; natibus parvis, elevatis; dentibus cardinalibus bifidis; lateralibus longis, minute seritis rectisque margarito purpurea.

*Cyrena Jayensis* (Jayana), *Lea, Trans. of Amer. Phil. Soc.* v. 108. pl. 17 f. 52; *Observ. of Gen. Unito.* i. 220. pl. 17 f. 52.

Hab. In fluviis insulæ Sumatrensis.

(1652) *Batissa violacea*.

B. testa ovato-transversa, elliptica, compressa inæquilateralis, crassa, solida, antice posticeque obtusa; margine superiore utroque declivi; umbonibus tumidulis, decorticatis, parum obliquis; latere antico lata sulcata, postico irregulariter striato; epidermide crassa, viridi-fuscescente, polita; valvis intus purpureo-violaceis vel vivide purpuratis; cardine crasso; dentibus inæqualibus, lateralibus transversim sulcatis.

*Venus reticulata*, *Born. Test. Mus.* p. 69.  
*Wood, Ind. Test.* pl. 8. f. 66.  
*Dosina puerpera*, *Gray, Cat. Cyth. Anal.* viii. 308.  
*Hab.* Oceanus Indicus; insulæ Borbonica et Madagascariensis.  
(1683) *Venus lacerata*.  
*V.* testa Veneri puerperæ affini, minus autem ventricosa et margini ventrali posticoque magis arcuatis; margine ligamentali subrecto et minime declivi; lamellis concentricis confertioribus et postice asperimis; superficie externa albida, lineis ferrugineis aut brunneis angulatum strigata; extremitate postica intus extusque immaculata.  
*Venus lacerata*, *Hanley, Ind. Test. Suppl.* pl. 16. f. 23, *App; Proc. Zool. Soc.* 1844, p. 161; *Sow. jun. Thes. Conch.* p. 704, pl. 152. f. 3, 4.  
*Hab.* Amboina; insulæ Moluccarum.  
(1684) *Venus magnifica*.  
*V.* testa suborbiculari, subcordata, tumida, solidissima, valde inæquilaterali; margines versus

purpureo tincta, umbones versus albida, brunneo sparsim maculata; lineis concentricis, sulcisque radiantibus decussata; lineis antice undatis et paulo elevatis, postice obsoletis, medio planulatis et sursum speciantibus; sulcis frequentibus profundis; margine ventrali arcuato, intusque crenato; dorsali, antice convexo et declivi, postice convexo et vix declivi; latere postico majore obtuso; natibus maxime curvatis; pube lunulaque prominente, cordiformi, livido-purpureis; ligamento infosso; superficie interna albida, immaculata; dentibus ut in Venere puerpera.

Venus magnifica, *Hanley, Proc. Zool. Soc.* 1845, p. 21.

*Sow. jun. Thes. Conch.* p. 704, pl. 152, f. 5.

*Hab.* Insula Ticao, Philippinarum.

(1685) *Venus Listeri*.

V. testa ovato-cordiformi, tumida, solidiuscula inaequilaterali; cingulis transversalibus foliaceis crispis erectis distantibus cincta, longitudinaliter dense striata; latere antico brevi, obtuso, angusto, postico lato, truncato, flavescente fusco pallido nebulata, aliquantisper immaculata; intus alba, postice violaceo tincta; lunula cordata, impressa, lamellosa, in medio carinata.

*Hab.* Mare Chinense et Japonicum.

(1701) *Meretrix Lamarckii*.

*M.* testa ovato-trigona, transversa, inaequilaterali, lateraliter depressiuscula, tævigata, fulva vel rufo-fuscescente, aliquantisper pallide radiata; latere antico obtuso, postico acuminato, angulato, umbonibus minimis, acutis, oppositis; lunula

## MOLLUSCA.

elongato-lanceolata, inter, valvas rimosa in medio prominente; sinu pallii, lato paulo profundiore quam in aliis speciebus.

*Cythera morphina*, Sow. jun. (non Lamk.)  
*Thes. Conch.* p. 620, pl. 129, f. 59, 60.

*Hab.* Mare Chinense (Cuming).

An eadem junior *Meretrix tenuis*, Gray?

III. *Testa trigona, transversim sulcata.*

(1702) *Meretrix Philippinarum.*

M. testa cordata, inaequilaterali, ventricosa, crassiuscula, pallide livida, radiis et lineis angulatum flexuosis, saturatioribus variegato, concentricè costellata; costellis convexis, confertis; interstitiis laevigatis; lunula brevi, cordiformi, alba, rima lividopurpurascens; margine ventrali integro, arcuato superficie interna albida, macula livida sub umbonibus notata.

*Cytherea Philippinarum*, Hanley, *Proc. Zool. Soc.* (1844) 110. Wood, *Index Test. Sup.* pl. 19, f. 36.

Sow. *Thes. Conch.* p. 627, pl. 136, f. 176.

*Hab.* Insulae Philippinae (Cuming).

(1703) *Meretrix lyrata.*

M. testa ovali-subtrigona, crassa, ventricosa, fulvo-cinerascente, concentricè subundatim sulcata; latere postico subangulato, fusco; lunula vix distincta.

*Meretrix lyrata*, Sow. *Thes. Conch.* p. 621, pl. 129, f. 61.

*Hab.* Insulae Philippinae.

(1704) *Meretrix grata.*

M. testa minima, ovato-trigona, depressiuscula, inaequilaterali, nitidissima, late profundeque transversim sulcata; sulcis regularibus, rotundatis, interstitiis subaequalibus separatis, simplicibus, rubescentibus, interstitiis pallide luteis; umbonibus acutis, parvis, angustis, elatis; lunula plana, ovato-angusta, elongata livida; area planulata, laevigata; valvis intus albis, macula angusta castanea in margine postico; sinu pallii latissimo, semicirculari.

*Meretrix grata*, Desh. *Proc. Zool. Soc.* 1853.

*Hab.* Mare Chinense. Coll. Cuming.

(1705) *Dione umbonella.*

D. testa cordata, tumida, inaequilaterali, basi purpurascens, superne alba, postico latere laevi, antico transverse sulcato; umbonibus tessellatis.

*Cytherea umbonella*, Lamk. *An. s. Vert.* ed. 2, vi. 319, no. 55.

Hanley, *Descr. Cat.* p. 102.

Var. Testa latior, alba, postice uniradiata, intus alba.

*Hab.* Mare Chinense; Nova Hollandia.

### (1711) *Dione florida*.

D. testa ovato-transversa, compressiuscula extremitatibus obtusa, alba, spadiceo inæqualiter radiata, maculis minimis pallidioribus notata, transversim et regulariter sulcata; sulcis latis, planulatis, antice profundioribus, postice aliquantisper evanescentibus; lunula ovato-cordata, spadicea vel alba, aut lineolis, rubescentibus variegata area excavata, lineolis undulatis, numerosis, rubescentibus ornata intus in fornice alba, postice et ad margines profunde violacea.

*Hab.* mare Rubrum; Mazambique, Madagascar. (Australia, *Lamk*).

### (1712) *Dione grata*.

D. testa transversim ovata, inæquilaterali, inflata, suboviformi, flava longitudinaliter violaceo-fuscescente radiata, transversim regulariter sulcata, sulcis regularibus, approximatis, depressis umbonibus tumidis, obliquis lunula magna, cordata, roseo-purpurascens area paululum excavata, lineis rubris distantibus flexuosis; valvis intus postice violaceis.

*Cytherea pectoralis*, *Sow.* (non. *Lamk.*) *Thes. Conch.* p. 625. pl. 130. f. 75.

*Hab.* Insulæ Philippinæ (*Cuming*).

### (1713) *Dione Erycina*.

D. testa ovali, crassa, concentrice planulatis sulcata, medio fusca, ad margines aurantia, prope marginem dorsalem fusco, et

## MOLLUSCA.

albo maculata, omnino fusco et albo interruptim radiata; latere antico brevi lunula distincta, aurantia.

(1865) MONG-NYEN, BURMESE. (*Sinapis orientalis*).

(1866) MONGOLS. Dr. Latham regards the indigenous Americans, as Mongols who have emigrated direct from Eastern Asia.

(1867) MOONDUN, HIND. A mahomedan rite of shaving the child's head on the 6th or 40th day after birth.—*Herklots*.

(1868) MOONKIR AND NUKIR, according to Mahomedan belief, are two angels who question the dead on their interment, as to their good and bad actions in life.

(1869) MOORSHUD, ARAB. Amongst the Sunni Mahomedans, this person is a religious instructor in a family. Amongst the Shiahs, there are reckoned twelve, viz., Ali and his eleven descendants.

(1870) MOOSUL, is situated on the right bank of the river Tigris; its population and trade has greatly diminished since the time, prior to the discovery of the Cape passage, when it was the thoroughfare for the caravans, between Europe and India. It formerly enjoyed a high reputation for the manufacture which derives its name from the town and is known in France as

## MUSA PARADISIACA.

mousseline and in English as muslin. At a short distance is the mound and village of Nebbi Yunus, in which is a mosque, which covers the supposed tomb of the prophet Jonah.

### (1871) MORINDA CITRIFOLIA.

Noana marum, or Munja | Maddichettoo, TEL.  
pavettay, TAM.

A small tree of common occurrence, the wood and root much used for dyeing red, the wood is deep yellow, easily worked and used for common purposes.—*M. E. J. R.*

### (1872) MORINDA UMBELLATA.

Noona Maram, TAM. | Chota Alka, HIND.  
Patangi Vriksha, CAN. | Molongoodoo Akoo, TEL.

The compact grained wood of this tree is of a beautiful yellowish colour and is frequently made into chairs.—*Rohde, M.S.S.*

(1873) MOTHER O'PEARL shells and tortoise-shell are brought to China from the Archipelago and the Islands of the Pacific, but a large part is re-exported in the shape of buttons, combs, and other productions of Chinese skill.—*Williams.*

### (1874) MUCUNA PRURIENS?

Quah-lay, BURM.

This abounds every where in the jungle. In a tender state the natives use it as food.—*Malcom's Travels in South Eastern Asia*, v. 1. p. 183.

(1875) MUNCHETTY MARAM, the Malayala name of a Malabar tree which grows to about twenty-five feet in height, and eighteen inches in diameter; it is used by the natives for coasting vessels and house building: it is of little value.—*Edge, Mal. Can.*

### (1876) MUNJENATIE WOOD.

Munjenatie marum, TAM.

This wood is used by the natives for making doors, stocks to matchlocks, and for other purposes.—*Ains. Mat. Med.* p. 208.

(1877) MUNJUN. *Hind.* Dentifrice made of charcoal of betel nut, of almond shell, or of frankincense and alum.

(1878) MUREED or disciple. The Mahomedan custom of making mureeds is performed, in the presence of others or alone in a closet by the Moorshud or religious teacher.

### (1879) MURRYA.

Mai-Kai, BURM.

Is not a large tree, but is highly esteemed for handles to spears, knives, &c. The grain is like box wood, but tough and elastic. Found only in the lower Burmese provinces.—*Malcom's Travels in South Eastern Asia*, v. 1. p. 190.

### (1880) MUSA PARADISIACA.

Nep. Yau, BURM.

Is one of the most valuable gifts of providence to a great part of the globe, growing wherever the mean temperature exceeds 65°. The stalk seldom exceeds seven or eight inches in diameter, and twenty feet in height, bears but one bunch of fruit, and dies. The stem is cut close to the ground, but from the same root, however, the

## MUSICAL INSTRUMENTS.

tree is renewed many years. The leaves, when young, are the most beautiful in India, expanding, with a smooth surface, and vivid green, to six feet in length, and two or more in breadth, but, soon after attaining full size, the edges become torn by the wind. The flower is very large, purple, and shaped like an ear of Indian corn. At the root of the outer leaf, a double row of the fruit comes out half round the stalk or cob. The stem then elongates a few inches, and another leaf is deflected, revealing another double row. Thus the stem grows on, leaving a leaf of the flower and a bunch of the fruit every few inches, till there come to be twenty-five or thirty bunches, containing about one hundred and fifty or one hundred and eighty plantains, and weighing from sixty to eighty pounds. The weight bends over the end of the stem, and when ripe it hangs within reach. Like the palms, it has no branches.

Humboldt calculates that thirty-three pounds of wheat, and ninety-nine pounds of potatoes, require the same surface of ground, that will produce four thousand pounds of ripe plantains, which is to potatoes as forty-four to one, and to wheat as one hundred and thirty-three to one. What a mercy is such a tree, in a country where hard labour is oppressive by reason of heat! There are as many varieties of this fruit in Burmah as there are of the apple in England and America; some preferred for cooking, others for eating in a raw state; some sorts grow wild, but in general it is exclusively the result of culture.—*Malcom's Travels in South Eastern Asia*, v. 1. pp. 176, 78.

(1881) MUSA SAPIENTUM. Is common in the southern districts of Burmah, but is not much cultivated. It is found wild, and in that state has seeds, which the cultivated plantains never have.—*Malcom's Travels in South Eastern Asia*, v. 1. p. 178.

(1882) MUSHAEKH, ARAB. A patriarch or devout man, a religious teacher.

(1883) MUSICAL INSTRUMENTS of the Mahomedans of India.

### WIND INSTRUMENTS.

(1884) *Zufereee.*

(1885) *Pultee*, a leaf of the *Cholum* (*Holcus saccharatus*, *Lin.*) held between the lips and sounded.

(1886) *Moorchung*, or jew's harp.

(1887) *Shuhnæe*, a kind of clarionet, a cubit long, and having a leaf mouth-piece, vulgarly called *Soornæe*.

(1888) *Soor*, a bass or drone to the *shuhnæe*.

(1889) *Algon*, a small flageolet, a span long.

(1890) *Nagaysur*.

(1891) *Poonggee*. Of this there are two varieties, one made of leather and sometimes accompanies the *kunchnee-ka-ta*; the other of pumpkin, usually played upon by jugglers and snake dancers, &c.

## MUSICAL INSTRUMENTS.

(1892) *Qurnā*, a straight or curved horn, twelve feet long.

(1893) *Toorree*, or *Toortooree*, commonly denominated by Europeans *colleryhorn*, consist of three pieces fixed into one another, of a semicircular shape.

(1894) *Baukā*, is the preceding one, but the upper piece turned from the performer, forming it into the shape of the letter S.

(1895) *Banslee*, or flute.

(1896) *Sunkh*, or conch shell. It is frequently used by devotees; also as an accompaniment to the *tumkee*. Sometimes they play trios and quartettos on the shells alone.

(1897) *Nursinga*, a sort of horn.

DRUMS, GUITARS, CYMBALS, CASTANETS,  
&c., &c.

(1898) *Chitkee*, or snapping the fingers.

(1899) *Talee*, or clapping the hands.

(1900) *Khunjuree*, a sort of small tambourin, played upon with the fingers.

(1901) *Duff*, or *uffra*, or tambour de basque; "tympanum," according to Gentius, *Sadi Rosar. Polit.* p. 303. A sort of bass tambourin played upon with a stick.

(1902) *Daeera*, the largest variety of tambourin, being from a foot and a half to two feet in diameter, played upon with a stick.

(1903) *Dhol*, a larger drum than the following, both sides covered with leather, and played upon with the hands.

(1904) *D'holuk*, or *Dholkee*, smaller than the preceding, and only one side covered with leather.

(1905) *Meerdung*, the kind of drum which is an accompaniment to the *kunchneea ku taefa*, q. v.

(1906) *Pukhawaj*, a kind of drum, a timbrel.

(1907) *Tubla*, a couple of drums, played upon at the same time, one with each hand.

(1908) *Nurga*.

(1909) *Nugara*, or a kettledrum.

(1910) *Ghurreeal*, a plate of brass for beating time.

(1911) *Tukkoray*, or *Zayrbum*, are small kettle-drums; one is called *Zayr*, the other *bum*.

(1912) *Dunka*, or a bass kettle drum middle size, between the *nugara* and *tukkoray*.

(1913) *Tasa*, or *Tasha Murfa*, a drum of a semicircular shape, played upon with two sticks, and invariably accompanied by the next (*murfa*).

(1914) *Murfa*, a drum like a *d'hol*, covered at both ends with leather, but played upon only on one side with a stick.

(1915) *Tubul*, an enormously large variety of drum, used in the field of battle.

(1916) *Tumkee*, a small circular brass plate, played on by striking it with a piece of wood, having a knob at the end.

(1917) *Dhubboos*, consists of a rod of iron about a foot long, with a knob at one end and a sharp point at the other, having from fifty to a hundred hollow rings which when shook rattle

## MUSK DEER.

against one another: used by *fugeers*, who wield it about, striking their abdomen of a sudden with the sharp point.

(1918) *G'hurra*, or empty earthen vessels, or water pots, played upon with the hand.

(1919) *Si-tara*, or *Yek Tara*, when with one steel wire, called by the latter name: sometimes it has nine or eleven steel wires; but generally three, whence its name, from three, and string.

(1920) *Tumboora*, a sort of *seetar* (guitar), having catgut strings instead of wire.

(1921) *Sarung*, or *Sarungee*, a musical instrument like a fiddle, played upon with a bow.

(1922) *Rubab*, a kind of violin, a rebeck.

(1923) *Been*, or *Vina*, a sort of *seetar* but having two dried hollow pumpkins (*Cucurbita melopepo*, Willd.) fixed to the end of it, with five or seven steel strings; described by Sir William Jones in the *Asiat. Res.*

(1924) *Keenggree*, as the preceding, but having three or four pumpkins, and only two steel strings generally used by Hindoos.

(1925) *Qanoon*, a species of dulcimer, or harp.

(1926) *Urugan*, a kind of organ.

(1927) *Ragmala*.

(1928) *Chukara*, a kind of violin.

(1929) *Thalee*, a flat earthen dish on which they rub and rattle a stick with both hands.

(1930) *Theekree*, two bits of sticks or fragments of earthen vessels used as castanets.

(1931) *Doroo*, a small double headed hand drum.

(1932) *Surod*, a kind of guitar (or *seetar*), having catgut or silk strings.

(1933) *Duppra*.

(1934) *Munjeera*, or *Jhanjh*, a kind of small cymbals in the shape of cups, struck against each other, and accompanying most bands.

(1935) *Tal*, cymbals used by devotees, and frequently an accompaniment to the *taefas*.

(1936) *Ghugree*, one or two hollow rings with pebbles in them, worn on one or both thumbs, and rattled.

(1937) *Goonghroo*, little bells fastened to a string, which is wound round the wrists and ankles, and which jingle at every motion of the limbs.

(1938) *Saz*.

(1939) *Seekhan*, a piece of iron about a cubit long, with which *fugeers* pierce their necks and cheeks.

Also;—An Arab musical instrument, used by the Arabians who frequent the Malabar Coast.

## (1940) MUSK DEER.

The musk-deer, called in Nepal *Kustoora*, is in size about as long as a small gazelle, beautifully formed, very active, and graceful in all its movements, and particularly shy. It inhabits all the most unfrequented parts of the Nepal hills, the male being much smaller than the female.

## MUTHUNKA PILLOO.

bag, which lies near the naval and is about the size of an egg. This musk is found only in the male deer, and, unless cut off before the animal is dead the whole is absorbed in the system, and the pod becomes useless. They are therefore almost invariably taken by nooses.

The natives have many curious traditions regarding this deer, especially as to the manner of the generation of the musk pod. The musk-deer, although one of the most timid and harmless, is at the same time one of the most deadly enemies the viper and adder have in the hills, and its mode of destroying them is curious. The ground on which the musk-deer are generally found, contains likewise large numbers of the small hill adder, a reptile little more than eighteen inches long, but very venomous. It throws itself in the way of man or beast, and invariably bites them. The musk-deer, however, seek for and destroy the adders, wherever they find them, in the following manner. The deer travel generally in pairs; the first that discovers an adder, gives a sharp snort through the nostril, when the other deer immediately comes to its side. The two now commence a series of the most eccentric gambols, jumping and skipping about, over each other's backs, and running round the viper in a circle (I may here mention that the inner hoof of the musk-deer is black and hard, and as sharp as a knife), and after jumping over the adder for five or six minutes, the male strikes it with the fore-foot so rapidly, that the eye cannot follow it, and the adder is thereby immediately destroyed. He then, with two blows, severs the head from the body, after which he displays his triumph and satisfaction by a series of gambols round and over the dead adder and then lies down.

On these occasions the musk-deer is invariably followed by a large buzzard or kite, who, as soon as the deer lies down, flies to and carries off the headless body of the dead adder to the nearest rock and there devours it. The charge of carnivorousness, laid to the poor musk by the ignorant natives, is thus accounted for and removed. The favourite food of the musk deer is a bulbous kind of wild garlic, for the digging up of which nature has provided the male with two small tusks in the upper jaw, about three inches long, and of the thickness of a common quill; with these he digs up the bulb, which smells as powerfully, when fresh, as the strongest musk, and from this food undoubtedly the glutinous and musky matter contained in the bag of the deer is generated.—*Smith's Nepal*.

(1941) MUSTARD OIL. Excellent oil is expressed in various parts of India from the seeds of different species of sinapis, especially from the black mustard seed. *S. glauca*, *S. bichotoma*, and *S. juncea* are extensively cultivated in the East for their oil.

## MYRRH.

cultivated in Chittoor by Miss Pereira. It produces abundantly, and the grain is cooked in the same way as paddy and raggy.—*M. E. J. R.*

(1943) MUZHAB. Arab. See DEEN.

(1944) MYHLENAH in Tamil, Mylelu in Malayala.—This wood is of a greenish tinge, and very close-grained; it grows to about twelve or fifteen feet long, and two and half feet in diameter. It produces a fruit like green pepper; its leaves resemble the mangoe: the wood is generally considered strong and durable, and the native carpenters procure from it the small crooks and branches for the knees and timbers of boats, &c. and the large limbs for the frames of native vessels. The tree is scarce in the north part of Malabar and Canara, and not known in Ceylon.

(1945) MYOUK-GNO, or MOUK-CHAN, *Burm.* Is a large *Burmese* tree of excellent timber. Bark, perfectly smooth; flower, very small on a long stem.—*v. 1. p. 192.*

(1946) MYOUK GO-MYEN, *Burm.* A smaller vine, bearing in its pod but one bean, the size of half a crown. Monkeys are said to be very fond of it, but Burmans do not eat it.—*v. 1. p. 183.*

(1947) MYRICA SAPIDA.

Kai-phul, *HIND.*

The fruit is edible, with a sweetish bitter taste: it ripens in June. In the Himalayas it is generally met with at an altitude of from 4000 to 6000 feet, and its bark is exported to the plains as a dye and as medicine.

(1948) MYROBOLAN EMBLIC.

Nelliekai, TAM.	Aunwera, HIND.
Aoonla, DUK.	Woosherikaia, TEL.
Amluj, ARAB.	Amalaci, SANS.
Amuleh, PERS.	Phyllanthus emblica. LIN.

This is reckoned a fruit and is frequently used as a pickle.

(1949) MYROBOLAN BLACK.

Zengi Har, BENG.	Unripe dried fruit of <i>Terminalia chebula</i> .
------------------	---------------------------------------------------

(1950) MYROLE or MIROLE, in Tamil and Malayala, is a Malabar wood of much value, but scarce. It is very heavy and strong, and grows to about twelve inches in diameter, and fifteen or twenty feet high. It is generally used where strength and durability are required.—*Edge. Mal. and Can.*

(1951) MYROSPERMUM. The species are trees with dotted leaves.—*Eng. Cyc. Vol. III, page 1028.*

(1952) MYRRH has long been in repute in low fevers in Europe, and occasionally in agues, Dr. Kirk has found it very useful in the typhoid state which is frequently the second stage of paroxysmal fever in this country, and also in the low adynamic fever of jails. He has also hazarded the conjecture that myrrh is an element of Warburg's Fever Drops, but apparently without any sufficient foundation.—*Ind. Ann. Med. Sci.* for

## N.

(1953) NAGAS, a hill tribe of Assam.

(1954) NAIL-OO, Burmese. This tree attains a diameter of eighteen or twenty inches. Blossom very beautiful and fragrant, yellow, size of a large rose; grows only in wet places. Timber is very worthless.—*V. l. p. 92.*

(1955) NAIDAM PAINI, the Malayala name of a tree which means long Paini. It grows to about two feet in diameter, and seventy feet high, and produces a sort of varnish which is used with the wood-oil before named, for paint or wood. The natives use the spars for rafting timber down the rivers, and for the yards of small vessels. It is a wood of little value, being neither strong nor durable.—*Edye. Mal. Can.*

(1956) NAKHL OOL SHAYTAN, ARAB.  
Devils Date.

This Dwarf-giant of palms grows near Zanzibar. It has no trunk, but the mid rib of each branch is thick as a man's thigh. Eccentric in foliage and frondage, it projects over the waves its gracefully curved arms, sometimes thirty and forty feet long.—*Black. Mag. March 1858, p. 285.*

(1957) NAMI, a root of the form of a large potato, which grows in Mindoro, cultivated also in Timor and in the Moluccas. It is said to be the Manioc or Cassava of South America.

(1958) NANAHI, the Tamil name of a tree, probably the *Morinda citrifolia*, which grows in Travancore and Malabar to about twelve feet in height, and ten inches in diameter. It is generally curved in its growth, and very soft and light. It resembles the American red-birch as to its silvery grain. The native carpenters use it for the frames of small vessels. It is of little value in consequence of its early decay.—*Edye M. and C.*

(1959) NA-NAH. Burm. Is a very large tree, thorny. Fruit deep red, size of a small plum, skin very thin, full of hard, white triangular seeds. Prized only by the Natives.—*V. l. p. 181.*

(1960) NARAH, the Malayala name of a tree that grows to about twelve feet high, and ten inches in diameter. It is curved in growth, and is used for the frames of vessels. It is not very durable, and ranks as one of the inferior sorts of jungle wood.—*Edye. M. and C.*

(1961) NARCISSUS. From the habit of planting the Narcissus upon tombs and shrines, it has acquired a certain sacredness of character. It is true that the Hindus have few tombs. They have shrines however, many of which have been adopted by the Mahammadans. The Narcissus is common in the Punjab.—*Ben. As. Soc. Jo. No. 11, of 1854, p. 146.*

(1962) NARDOSTACHYS JATAMANSI. This species of valerian smells strongly of patchouli, and is a very favourite perfume.—*Hooker Him: Jour: Vol. 1. page 217.* The true spikenard of the ancients is supposed to have been obtained from the *Nardostachys Jatamansi*.—*Simmonds' Comm. Product, 572.*

(1963) NASTURTIIUM TROPÆOLUM.

Natraloo, HIND. | Vally cayang, TAM.

Sweet Potato is the root of a creeper, which is boiled and eaten by common people. It is of two kinds or colours, white and red. The white is supposed to have been brought from some foreign land, and under this supposition it is called Walaitee natraloo or European or Foreign Natraloo, and the other Nat Ka Natraloo or country Natraloo. The white is the better of the two.

(1964) NAUGLEA CORDIFOLIA, RUBIACEÆ. Roxb. C. 53.

Munja cadumbay or | Kolkadum, BENG.  
adumbay, TAM. | Darooga, TEL.

This grows to be a very large tree, it is a native of the mountains of the coast of Coromandel, flowers during the wet season. The seeds ripen about April. The wood of this tree is exceedingly beautiful, its colour is like that of the box tree, but much lighter and at the same time very close grained. It is to be had of a large size from one to two feet or more in diameter and is used for almost every purpose where it can be kept dry. For furniture it answers exceedingly well being light and durable.—*Rox: Rohde M.S.S. Dr. Wight* says that it gives a pretty, close grained, yellow wood, but soft. It is easily worked, attains a rather large size and is much used for common purposes, on trial it sustained a weight of 320 lbs.—*Wight.* And Mr. Rohde remarks on Dr. Wight's note that either the Cumboo or Bundaroo of the Circars is probably the wood here described. These are abundant in the districts of Vizagapatam and Rajahmundry, both are much affected by alternations of dry and wet weather and are only suited for work which is sheltered, for bedsteads, &c. they are sufficiently good, indeed varnished they resemble Rose—the Bundaru has a deeper colour and is, he believes, *Cinchona excelsa* of Roxburgh; the *Hymenodction excelsum*, of Wight and Arnot; but wood cutters and merchants do not distinguish these woods on the Godavery.—*Rohde.*

This resembles a young Sycamore and is very common in Behar.—*Hooker, Him. Jour. Vol. p. 26.*

Kadumbay wood, ENG. | Kadumbay marum, TAM.

# NAVY, INDIAN.

of a very beautiful wood for furniture; sometimes, though rarely, brought to the sea ports of the lower provinces of the Peninsula, from Ceylon.—*Ains. Mat. Med.* p. 211.

## (1966) NAUCLEA PARVIFLORA, ROXB.

Bota cadamie is the Telingoo name of a large tree, a native of the Coromandel coast. The wood of it by Dr. Roxburgh's account, is of a light chestnut colour, firm and close grained but soon rots if allowed to get wet.—*Ains. Mat. Med.* p. 212. According to Mr. Rohde, this grows to be a very large tree, is a native of almost every part of the Coast of Coromandel, but chiefly up amongst the mountains. Flowers during the cold season. The wood is of a light chestnut colour, firm and close grained, is used for various purposes, where it can be kept dry, but exposed to wet it soon rots.—*Roxb., Rohde. M. S. S.*

(1967) NAVELLU MARAM, the Tamil name of a tree which signifies "tongue-wood." It grows to about fifteen inches in diameter, and twenty feet high: it is considered a strong and durable wood, and more particularly so under water. The native carpenters prefer it for the frames of small vessels in consequence of its strength and durability.—*Edye. Mal. and Can.*

(1969) NAW OR NAGOO MARAM. Pterocarpus' species, a very strong and durable wood, common on the lower elevations of the Neilgherries: an ordinary sized tree—*McIvor. M. E.*

(1970) NELA, the Tamil name of a tree which is of a dark red colour, and is considered a good wood for boat-work; it produces a small fruit, which the natives eat in a raw state.—*Edye M. and C.*

(1971) NELUMBium SPECIOSUM. THE-KYAH, Burmese. Is a sort of lily, growing in the water; flower very large, pink and white; fruit is as large as a fist, forming an exact hemisphere, on the flat surface of which about twenty-four seeds are imbedded, which, when ripe are black and hard. Prized for eating. The flowers are a favourite offering at the Burmese pagodas.—*Malcom's Travels in South Eastern Asia, V. 1. p. 183.* *Nelumbium Speciosum*, is the Sacred Tawmery Plant. The long fine filaments contained within the cells of the stem are drawn out and thread spun from the filament.

(1972) NEPAUL. The Kingdom, or State of Nepaul, occupies a tract of country about seven hundred and fifty miles in length, and one hundred and seventy in breadth, situated between 26° 31' and 30° N. latitude. It is bounded on the north by a part of Thibet, from which it is separated by the Himalaya chain; on the east, by Bootan and the little Rajahship, or state of Sikkim, from which it is separated by the river Teesta; on the south, by the British-Indian province of Tirhoot, from which it is divided by the Terai, an immense forest, the eastern part of which is called the Moray district; and on the west, by the kingdom of Oude. The divisions of Nepaul are Jumla, Goorkha, Nepaul, Muckwanpore, and Morung. The principal rivers which traverse the territory are the Kalce and Surgoo, which, meeting at a place called Pramadee, form the Goggra and Gunduck. The Gunduck is supposed to rise in the Himalayas, and flows into the

Ganges near Patna. The upper part of the river is called Saligramee, from the fossil ammonites called Saligrams which are found in it, and which the Hindoos hold in veneration.

*Note.* The boundary line to the north is not in our maps properly laid down. It appears by a recent communication from a Nepaul officer, who accompanied the mission to England in the year 1850, that the line should leave the boundary as laid down by us at Gossington, from which place, westward, both slopes of the main chain of the Himalayas belong to Nepaul. The boundary then runs along a ridge to the north of the Himalaya, including Mustang, a place about thirty miles from the foot of Dhawalagiri, and much resorted to by pilgrims. From Mustang the frontier continues west, including the valley of Humla, with the head waters of the river Gogra. From this it appears that the distance from the Nepaul and Thibet frontier, to the Bramaputra or Dsanpo river, is about fourteen miles. The two largest villages to the north, which carry on a great trade in salt with Thibet, are called Thak and Mooktinatt. It should be borne in mind that this boundary is claimed for Nepaul by a Nepaulese, whose assertions there have been no means of disputing. It is not impossible that he may have defined the boundary accurately, but as the extension of their territory has always been a favourite purpose with the Nepaulese, their own definitions must always be received with caution, if not with suspicion.

The geographical position of the British territory, relating to Nepaul is now as follows:

To the extreme west of Nepaul, lies Almorah, a hill-station, wrested from the Nepaulese in the wars of 1815—16; to the extreme east is Darjeeling, another hill-station, used by the Supreme Government of India as a sanatorium for invalids. The principal British cities and military stations which border on the Nepaul territory along the line of the Ganges, are, Berhampore (contiguous to the Morung district), Monghyr, Patna, Dinapore, Ghazeepore, Benares, Allahabad, Cawnpore, Lucknow, Futtighur, and Bareilly; the last named town lying opposite to a Nepaulese fort called Doti, and a few miles from the hill-station of Almorah.

The Terai, or Turry, or Turyanee, is a long strip or belt of low level-land. The word, probably, signifies low or marshy lands, but it is sometimes applied to the flats lying below the hills in the interior of Nepaul, as well as to the level tract bordering immediately on the British frontier. It abounds with large and lofty forest-trees, the chief of which are the Saul and the Bechiacori pine. Some of the Saul spars reach the length of seventy to eighty feet, and are generally considered unequalled for strength and durability. In this respect, however, they must yield to the teak, for there is this peculiarity in

employed in bulk for many years, rising into large fissures longitudinally, and falling a prey to the white ants. Small quantities of gold-dust are found in the Gunduck, which runs through the Terai, and Lignea Cassia is likewise produced in the jungle. The latter, under the name of Sing Rowla, is much used in Hindostan in spicery: the bark of the root does not differ widely from cinnamon, for which it has often been mistaken, but the bark of the trunk and branches possess little of the cinnamon flavour.

Beyond the Terai, and still bearing its name, is a range of hills of about the same width, at the northern base of which commences the valley of Nepaul. This valley, which is nearly oval in shape, is about twelve miles from north to south, and nine miles from east to west. Its circuit has been roughly estimated by the inhabitants at twenty-five coss, or from forty to fifty miles. The range of mountains to the north of the valley is stupendous; the ranges to the east and west are much less lofty, the immediate head of the valley to the westward being defined principally by a low, steep ridge covered with brushwood.

At the foot of the northern range, situated upon the eastern bank of a small river called the Bishenmuttee, in latitude  $27^{\circ} 42' N.$ ; longitude  $85^{\circ} E.$ , stands the city of Khatmandoo, the capital of Nepaul. It is not the largest of the towns in the valley, but enjoys the eminence of a metropolis, because it is the residence of the Rajah, or king, of Nepaul. In length, Khatmandoo may measure about a mile; its breadth is inconsiderable, nowhere exceeding half and seldom extending beyond a quarter of a mile. The name, says Colonel Kirkpatrick, by which the town is distinguished in ancient books, is Gorgoolputten: the Newars call it Yindaise, whilst among the Parbuttias, or mountaineers, it is styled Kulti poor, an appellation which seems to proceed from the same source with Khatmandoo, and derived, it is believed, from its numerous wooden temples, which are among the most striking objects in the city. These edifices are not confined to the body of the town, but are scattered over its environs, particularly along the sides of a quadrangular tank, or reservoir of water. The houses are of brick and tile, with pitched or painted roofs. On the street-side they have frequently enclosed wooden balconies of open carved-work, and of a singular fashion; the front piece, instead of rising perpendicularly, projecting in a sloping direction towards the eaves of the roof. They are of two, three, and four stories, and almost without a single exception are of a mean and poor appearance. The streets are exceedingly narrow, and very filthy.

The city of Patun is of the next importance. It occupies a rising spot of ground, situated about two miles S. by E. of Khatmandoo, and close to the confluence of the Munnohra, Tookcha, and

is that of the Chucro, or wheel of Narain. Patun is called Yellodaise by the Newars; and it is likewise occasionally distinguished from Deo Patun, by the appellations of Lallit-Patun and Lall-Patun. It is a neater town than Khatmandoo.

Bhatgong is perhaps still more superior to Khatmandoo, for though the least considerable of the three towns in point of size, yet its buildings in general have a more striking appearance; and its streets if not much wider, are at all events much cleaner than those of the metropolis, a distinction which it owes to its admirable brick pavement. Bhatgong lies E. by S. of Khatmandoo, at a distance of nearly eight road miles. Its ancient name was Dhurmapatun, and it is called by the Newars, Khopodaire; by whom it is also described to resemble in figure the Dumbroo, or guitar, of Mahadeo. It is the favorite residence of the Brahmins of Nepaul, containing many more families of that order, than Khatmandoo and Patun together.

Kirthipoor occupies the summit of a low hill, about three miles west of Patun. It was at one time the seat of an independent Prince; and its reduction cost the Goorkhali Prince so much trouble, that in resentment of the resistance made by the inhabitants, he barbarously caused all the males, whom he captured in it, to be deprived of their noses. Chobar is also situated on an eminence, which with that of Kirthipoor, forms a kind of saddle hill.

Nepaul contains, from its locality, every variety of climate. The fourth of it lies in the hot plains of the Ganges, and the remaining three parts lie on the slope of the Indian Andes, from the elevation of five thousand feet up to the limit of perpetual snow. It is alleged to contain from forty-three thousand to fifty thousand square miles, and to have two million inhabitants. It may be called the Switzerland of India; but its area is equal to that of three Switzerlands, while the amount of its population is no more than one-third part as great.—*Smith's Five Years at Nepaul*, p. 63, vol. 1.

*Climate and productions of Nepaul.* The height of Nepaul above the level of the sea is about four thousand feet. The thermometer, notwithstanding this height, ranges to 87 degrees. Its usual height about noon varies from 81° to 84°. A little after sunrise, it stands between 50° and 54°, but it is occasionally as low as 47°. At nine in the morning, it fluctuates from 62. to 66°. The mean temperature in March is 67°.

The seasons of Nepaul are pretty nearly the same as those of Upper Hindostan. The rains commence a little earlier, say in the month of May, and set in from the S. E. quarter; they are usually very abundant, and break up towards the middle of October.

Enormous fruit trees are found in the Terai. In addition to the Saul, and the Bechia-conri pine, are to be found the Sissoo, the

Setti-saul, the Phullamical, (an iron wood) the Kalikset, (a sort of black wood), the Sajk, the Burra, the Sunni, and the Moolta. Besides these, there is a small quantity of ebony. These woods constitute in a great measure the commercial wealth of Nepaul. Wood merchants congregate at the southernmost point of the forest near the river Gunduck because of the facility presented by that river of floating the timber to Calcutta.

The inhabitants of Nepaul consist chiefly of Brahmins and Khetries, with their various subdivisions of Newars, Dherwars, Mhargies, Bhootias, and Bhamas. The former of these compose the army, engross all situations of trust, whether civil or military, and are dispersed promiscuously throughout the country. The Newars are confined almost to the valley of Nepaul. The Dherwars and Mhargies are the husbandmen and fishers of the western districts; and the Bhootias, though some families of them are planted in the lower lands, occupy, generally speaking, such parts of the Kachar as are included in the Nepaul territories. The Bhamas are a sort of separatists from the Newars, supposed to amount to five thousand; they shave their heads like the Bhootias, observe many of the religious rites, as well as civil costume of these idolators, in a dialect of whose language they are said to preserve their sacred writings. To the eastward of Nepaul some districts are inhabited by Limboos, Naggunkotes and others.

The Newars are divided into several castes or orders, most of which derive their origin, like those among the more ancient Hindoos, from a primitive classification, according to trades and occupations.

The peasantry of the Parbattiahs, or hill people, are divided into four classes, denominated Awal, Doom, Seoom, and Charem. These are Persian terms, and denote, first, second, third, and fourth. The Awals are those peasants who possess five ploughs and upwards; the Doods, such as have from one to five; the Seooms are those who, without being proprietors of ploughs, are considered to be at the head of a few or more labourers; and the lands of Nepaul Proper are cultivated, almost without exception, by Newars; those to the westward, as Noorkale, &c. by the Parbatty tribe, called Dherwara.

The Ryots or peasantry are distinguished also into Koochrya and Perja. The former are those settled in Bertha proprietary, or other rent-free lands, and are not liable to be called on by government for any services, except the repair of roads, and attendance in the army upon particular occasions. The Perjas, who occupy lands actually belonging to the Prince, though perhaps in the immediate possession of Jagheerdars, are, on the contrary, obliged to perform various services, both at the call of the Jagheerdar and of the Prince.

The great aboriginal stock of the inhabitants of

## NEPAUL.

the mountains, east of the river Kali, as in Nepaul is Mongol. The fact is inscribed, in characters so plain, upon their faces, forms, and languages, that we may well dispense with the superfluous and vain attempt to trace it historically in the meagre chronicles of barbarians.

The Elthariahs are the descendants, more or less pure, of Rajpoots and other Kshatriyas of the plains, who sought refuge in these mountains from the Moslem, or merely Military service, as adventurers.

The Elthariahs speak the Khas language, and they speak no other.

The martial classes of Nepaul are, then, the Khas, Magar, and Gurung; each comprising a very numerous clan or race, variously ramified and subdivided.

It has been calculated that there are at this time in Nepaul no less than thirty thousand Dakhariahs, or soldiers off the roll by rotation, belonging to the above three tribes. There does not exist any insuperable obstacle to England obtaining, in one form or other, the services of a large body of these men; and such are their energy of character, love of enterprise, and freedom from the shackles of caste, that their services, if once obtained, would soon come to be most highly prized.

In the opinion of competent judges, they are by far the best soldiers in India; and if they were made participators of our own renown in arms, their gallant spirit and unadulterated military habits might be relied on for fidelity; and our good and regular pay, and noble pension establishment would serve to counterpoise the influence of nationality, especially in the Magars and Gurungs.

The beautiful furs, monthly obtainable in Khatmandoo, from Lassa and Digurchee, in Thibet, might be imported. These two large cities are great fur depots; they are only forty marches from Khatmandoo. It is, however, deserving of consideration, whether by encouraging a direct fur trade, we should not be unintentionally giving offence to Russia, for a very large portion of the Russian fur trade is derived from this part of Thibet, and certainly by far the most valuable furs are obtained there. Some of the most beautiful dresses made of furs are brought by the Native merchants from these cities; and he once purchased from one of them a fur cloak with thick silk lining for one hundred and fifty Moree rupees, in English money little more than ten pounds.

The list consists of 652 species.

89 Raptorial.

407 Passerine.

44 Gallinaceous.

77 Wading.

35 Palmipedes.—*Beng. As. Soc. Jour.* No. VI. of 1851.

(2010) *NEPHELIUM LONGANUM*. Sapindaceæ. Poovutty marum, Tamil. A moderate sized tree having a strait trunk and fine globular head. The wood is white, hard and close grained, but the carpenters, seem to be unacquainted with it.

(2011) *NEP YAN*, BURMESE; Plantain: *Musa paradisiaca*.

### (2012) *NERIUM ODORUM*.

Kurrubee, HIND.

Common in gardens in every part of India. The bark of the root, and the fragrant leaves are used by the native Indian practitioners as powerful repellants: applied externally. The root is very poisonous.—*O'Sh.* p. 445.

(2013) *NERIUM OLEANDER*. The oleander, rose bay, or spurge laurel.

*Νηριον Ροδοδενρον, Ροδοδαφνη.* Diosc.

Karzahra, HIND.

A native of the warm parts of Europe, of Asia Minor and the lower Himalayas, common in gardens all over India. The whole plant is impregnated with a dangerous principle which has not as yet been insulated, though many attempts have been made to procure it. Its activity and volatility are very great; it is even a popular belief that the vapour of the flowers in a close apartment will prove poisonous. Exter-

nally the leaves and bark have been used (and sometimes even internally) as a remedy in herpes and itch. The rasped wood is employed as rat-bane. The wood itself is used by some eastern nations as the best material for gunpowder charcoal.—*O'Sh.* page 445.

(2014) **NERIUM PISCIDIUM** of Dr. Roxburgh is used for its tough fibres, and contains a narcotic principle which proves pernicious to fish inhabiting tanks in which the fibres are steeped.—*O'Sh.* p. 445. *Nerium Pisidium* is the Echalat of the Cossia Hills, its bark contains fibres, used by the natives as hemp. It is a perennial climber.

(2015) **NETAVIL MARUM** or **CHUNDAO LEPURANDA SACCADORA**. This very common tree is the most gigantic of all in Wynaad jungles. Croramboor bags or sacks are made from the bark: wood not much used.—*McIvor. M. E.*

(2016) **NETTE PALE**, the Tamil name of a tree which produces the country gooseberry: the fruit is one of the most powerful acids of India. It grows to about twelve inches in diameter. The wood is not of any use.—*Edye. Mal. and Can.*

(2017) **NGADJU**, the name of the inhabitants on the Kahayan or Dyak river in Borneo.

(2018) **NICOBAR**. The amount of the whole population spread or scattered over the Nicobar Archipelago does not exceed the moderate number of 8,000 souls; of whom about 2,000 inhabit Carnicobar. Theressa had a population of about 500 souls.—*Jour. Ind. Arch. Vol. III. No 5, 1849.* The Nicobarians are strong and capable of carrying very heavy burdens. Some of them carrying without any trouble 200 cocoanuts.—The language used by the Nicobarians is polysyllabic, abounds in vowels, and its pronunciation is harsh and far from harmonious.—The chief food of the Nicobarians is the pulp of the cocount, yams, plantains, papayahs, fowls, and above all pigs, which abound in those Islands. It is not uncommon to see round a single hut, 40, 50, or 60 of them. The quantity of pigs killed and eaten is almost incredible. The Nicobarians, though voracious, separate the grease from the flesh, and keep it separately for culinary purposes; they never eat, or rather devour any part but the flesh, and that for a single festival day. There was seen and counted 75 large pigs killed for satiating the wolf like appetite of the inhabitants of an inconsiderable district of Theressa Island. In this respect, the Chinese could not be a match for the Nicobarians.—*Jour. Ind. Arch. Vol. III, No. 5. 1849, page 272.*

(2019) **NIGELLA**.

Magreela Kala-jira, HIND.

Seeds of *Nigella sativa*; black, irregularly angular, resembling grains of coarse gunpowder.—*Ben. Phar.*

(2020) **NIKAH**, ARAB. Nikah and Shadee are often in India used synonymously as mean-

ing the marriage or the marriage ceremonial of the mahomedans. The nikah, however, is the form of words used by the Kazee in uniting the couple and the shadee or rejoicings, are all additional, and may be lengthened or curtailed at the will of the relatives. About Delhi, the ceremony of Nikah would appear to be styled "*Burat*." The shadee ceremonial in India is generally used only where the bride is a spinster and of equal rank with the husband.

(2021) **NILA PALA**, the Tamil name of a small tree, the wood of which is very close-grained; it is used in house-work. The root of this tree is used as a medicine, and applied in cases of rheumatism (which are very prevalent after the monsoon sets in); this tree is only found in Travancore and there it is sacred.—*Edye. M. and C.*

(2022) **NIMROUD**. The mound wherein sculptures have been discovered at this ancient place is not far from the Tigris, and about four hours distant from Mosul. Xenophon, in his account of the retreat of the 10,000 makes mention of a pyramid in a town called by him Iarissa. It is most probable that the mound marks the site of that place.

The Birs Nimroud and mound are supposed by Travellers to represent the town of Babel, but others conjecture it to be the remains of a temple of the ancient Borsippa which is mentioned as having been near Babylon, and where Alexander halted on his road to Ecbatana when warned by the Chaldeans not to enter Babylon from the East.

(2023) **NITAM-PALA**, the Tamil name of a tree that grows to about twelve or fifteen feet long and fifteen inches in diameter: it is not of much consideration; it produces a small fruit which is used by the natives medicinally.—*Edye. M. C.*

(2024) **NITO CLOTH**. A cloth used by the wild natives in Mindoro.

(2025) **NOBUTS**.—Are a species of Kettle drum the use of which is confined to royalty, and even then they are used only on occasions of state. In the regulations for the government of Malacca in the 11th Annal it is laid down that when it is necessary for the Lacksamana to be in attendance the Nobuts ought to be present. the term, "to confer Nobuts," means, to give one the government of a country with the rights of royalty.—*Jour. Ind. Arch. No. 8 Vol. 5. Act. 1851.*

(2026) **NOSTOE EDULI** is used in China as food; *Gelidium corneum* enters, it is said by some, into the formation of the edible swallows' nests of the Japanese islands. Agar-agar moss is shipped from Singapore to the extent of 13,000 tons a-year. Irish moss, Iceland moss, Ceylon moss, and some others, are also of some importance. Iodine and kelp are prepared to a considerable extent from sea weeds; one species (*Fucus tenax*) furnishes large supplies of glue to the Canton market. and the orchilla weed is of great importance to the dyer.—*Simmonds*

(2027) NOW-ROZ, PERS. New year's day amongst the Mahomedans the day on which the sun enters the sign Aries.

(2028) NUTMEG. On the progress of the nutmeg cultivation and trade from the early part of the seventeenth century up to the present day.

It is the hitherto extremely limited consumption of nutmegs and mace, and of the latter especially, over the world, as compared with other tropical exportable produce, which has checked and perhaps ever will continue to check, any permanently large progressive increase of these spices.

The aid of arithmetical acumen would scarcely be required to shew that the culminating point of nutmeg cultivation has been nearly, if not already reached, so that should but a merely fractional portion of the area in E. Asia now under the rule of two nations respectively, nay, should the islands of Singapore and Pinang with the lands of P. Wellesley, only,—be fully planted and cultivated with nutmeg trees, the produce of the whole cultivation would be amply sufficient to glut all the markets of the world.

The facts we are about to exhibit have been chiefly obtained from official Dutch records, quoted by British authorities when the Dutch spice islands were under British rule, and from the official reports and statements of these British authorities themselves. The inferences from and observations on these documents are those of the Editor of the Indian Archipelago.

It is well known that the Dutch confined the cultivation of the nutmeg, when they got possession of the Moluccas from the Portuguese, in the end of 1598, to three distant islands.—Lonthoir or great Banda, Banda Neira, and Pulo Aye.

“The first of these presents a ridge of hills of various heights from one extremity to the other, the sides of which are cut into ravines through which descend a few small streams, the only ones on the island. The island is crescent shaped, is 9 miles long and  $2\frac{1}{2}$  miles across where widest. The highest hill or Neira does not exceed 800 feet and the south side is perfectly flat. Gunong Api is a single island or cone of volcanic matter rising from a rocky base and separated from great Banda by a narrow channel. It has the appearance of a heap of cinders and two thirds of it are perfectly black and bare of all vegetation, while a constant smoke rises from the crater.

Pulo Aye, according to Martin, and the S. side of great Banda yield the best nutmegs. Neira is  $2\frac{1}{2}$  miles long and about  $3\frac{1}{4}$  miles across where widest. Pulo Aye is nearly circular and is about  $1\frac{1}{2}$  mile in diameter.—*Present state of Banda* 1813.

Count Nogendorp *Coup d'oil sur le isle de Java &c.* vide Singapore “Free Press” 14th Dec. 1818, informs us in 1830 that Banda Neira lies in

4-30 S. Latitude and 128,18' Long. East of Paris.

“Gunong Api, is so named from the terrible volcano which is found there. Lonthoir is commonly called the *high land*,” other islands are Rosingain, Pulo Aye and Pinang.

“The island of Rosingain has been little inhabited since the extirpation of spices [spice trees] by the Company in 1632.

“The cultivation of the nutmeg is exclusively confined to Banda, Lonthoir and Pulo Aye. Gunong Api is unfortunate on account of its frequent eruptions and its insalubrity. It lies near to Banda and Lonthoir.

“Earthquakes are frequent and ordinarily precede or follow the eruptions. The strongest eruptions were in the following years:—

“1598, 1615, 1632, 1691, 1711, 1749, 1798, 1820. “That of 1691 was a terrible one.” *Coup d'oeil sur le isle de Java &c.*—vide Singapore “Free Press” 14th December 1848.

The intervals betwixt these periods of eruption are therefore consecutively 17, 17, 59, 20, 38, 49, 22, and the general average of these intervals is 31 years and a little more than a month. The most fatal earthquakes took place in 1629, 1683, 1686, 1743 and 1816.” The intervals therefore are 54, 3, 57, 73 years respectively.

Thence it appears that these convulsions arose from there having been no vent for the lava.

The Banda soil is stony. *Defence of the E. India trade, written in 1821, supposed by Thos. Mun.*

By the above average of eruptions and dating back to 1820, an eruption may be expected somewhere about 1857.

Mr. Mun for 1750 rated the total produce of the islands at 250,000 lbs of nutmegs besides mace.

The Dutch author Stavorinus acquaints us that the annual average produce during the early part of the last century was 700,000 lbs (Dutch) of nutmegs, and 180,000 lbs (do) of mace. But he adds, that in the year 1778 a hurricane destroyed all the trees excepting 8,000 which last number yielded an annual produce of 30,000 lbs of nutmegs with the usual proportion of mace. Allowing 10 per cent of trees for males, which is a very small proportion when trees have not from the first been regularly and systematically planted, the productive ones will have thus yielded  $4\frac{1}{8}$  lb. per tree of nutmegs. But if these 8,000 were all bearing or female trees the rate per tree would be  $3\frac{1}{4}$  lbs nutmegs.

Mr. Martin, (*Letter H. B. Martin, Resident at Amboyna, to the Supreme Government dated 24th March 1812.*) estimated the produce previously to the above year (perhaps the year immediately preceding it) at, for Europe 250,000 lbs nutmegs; for India 100,000 lbs, and mace 80,000 lbs, which would admit of a total produce of about 350,000 lbs nuts, the best sorts only being sent to Europe.

Mr. Martin also remarks that this quantity of 700,000 lbs has reference to the beginning of the 18th century. The English market was not then so particular as to quality as it afterwards became so that probably Nos. 1, 2 and 3 were sent to Europe about this period.

If the 3,000 trees yielded 30,000 lbs, then there were 168,000 trees in the early part of the above century. But the rate of bearing here brought forward does not quite tally with subsequent reported averages.

In Dutch official records Pulo Aye afforded the best nutmegs and yielded annually, from 45,000 trees, the quantity of 130,000 lbs or  $3\frac{1}{3}$  lbs (Dutch it is supposed) per tree of nuts.

At this rate therefore the number of trees just before the hurricane would only have been perhaps about 86,000. We cannot however fully rely upon this statement of Stavorinus, for it is supposed that at the period alluded to, the Dutch Government may have kept back part of their produce in order to obtain the highest monopoly price.

The Dutch estimate in this year 1805, (H. R. Martin,) prospectively to 1815, was—the two Bandas 530,000 nutmegs—Pulo Aye 180,000 do. with the usual proportion of mace. But this estimate does not appear to have been realized as will be shown when we come to examine the account by the Resident of Bencoolen, 1806—1812. Mr. Martin shews that the plantation betwixt these two years yielded upon an average 392,000 lbs (English) of nutmegs yearly with  $\frac{1}{4}$  of this quantity of mace.

It would appear that about these periods the exportations to Europe consisted of Nos. 1 and 2 only of nutmegs, or 259,000 lbs. and of mace 80,000 lbs. All the No. 3 and 4 sorts went to India. Mr. Hopkins allows Nos. 1 and 2 to be about  $\frac{4}{5}$ ths of the whole delivery, which seems to me too much according to Straits estimates, where it would be nearer to one half. But even with No. 3 included it would be little more than  $\frac{1}{3}$ rd.

This writer (Major Thom's reports, 1814. History of Java,—and referring probably to 1810,) who must have had ample opportunities of gaining information respecting the Spice Islands, also states that the cultivation of the nutmeg was confined to Lontai or the Great Banda, Neira and Pulo Aye, which last island he makes to be  $1\frac{1}{2}$  mile in diameter. He also allots to its area 45,459 trees, which on a rough calculation would give about 37 trees to an acre, for more could hardly without great crowding have been planted on the area. Indeed, with advertance to irregularities and breaks in the surface, the trees may have been still more closely packed.

He states the average produce in 1810 to have been for all the islands:—

300,000 lbs. of Nutmegs.  
85,000 lbs. of Mace

which would be a decrease of 50,000 lbs. of nutmegs on Stavorinus' average of exportation. He then goes on to observe that the estimated number of trees (males included I suppose) was then 500,000 "from *below* five years of age to upwards of twenty," which information is certainly vague enough and furnishes no precise data on which to found an estimate of the rate of production.

This writer (Mr. Hopkins, 16th March 1812,) acquaints us that the produce had been yearly increasing and cautiously estimates the average amount of produce for ten years prospectively ending in 1822, at betwixt six and seven hundred thousand lbs of nutmegs and for 1824 the quantity of 800,000 lbs.

Crawford's estimate for 1820 was 600,000 lbs of nutmegs and 150,000 lbs of mace, following apparently the Dutch estimate of 1815. But the latter were so far out in their prospective estimate for 1815 as to overrate it by 198,000 lbs of nutmegs.

The following report (The Bencoolen Resident's Reports to the Supreme Government of British India in the years 1814 and 1816,) is the only British official one amongst those already stated, which supplies us with any really precise and tangible data, but it still accords pretty closely in its main point with Major Thom's account. The difference betwixt the number of trees, as given by each is 50,000.

The Resident observes thus:—

	Trees.
There were then of female trees in bearing down to 10 years of age...	339,500
Monocious in bearing down to 10 years of age.....	52,000
	<hr/> 391,505
Males.....	32,000
Unknown from 5 to 10 years of age.....	39,500
Ditto ditto to 5 years old.....	87,500
	<hr/> 159,000

I would, before proceeding further, call the reader's attention to the fact that the female trees above enumerated, are not here reckoned in useful bearing until their tenth year, which accords with Count Hogendorp's account where he says the tree begins to bear about its 9th year and bears fruit for 50 years if sheltered, and that the males are about a 12th part of the whole, the sex of which were known.

The average produce for the three years immediately preceding 1814 was.

461,700 lbs. of nutmegs.  
123,100 lbs of mace.

(Where Dutch accounts are quoted it is the Dutch pound that is alluded to, where English

writers are quoted, unless specified to the contrary, the English lb. seems to be always meant.)

This would only give 1 lb and a little more than  $\frac{1}{2}$  lb for each bearing tree. But we might place the monocious trees nearly out of the account as they bear but a small quantity, or say that we allow ten, perhaps too many, of such for one good female tree.

This will leave 5,200 to be reckoned in the same category with the female trees, thus leaving a total of good bearing trees of 344,700, so that the produce per tree in this instance would be a fraction more than  $\frac{1}{4}$  lb of merchantable nuts and with mace in proportion. ‡

In the journal just quoted the No. of nutmeg trees then planted out was estimated at 570,500, of which 480,000 were in bearing. We are left in ignorance of the source of information. But this estimate would give a smaller produce per tree than that just described.

These results do not accord with the belief generally entertained by those who have had no means of testing the received opinions regarding the fertility of the nutmeg tree in situ, nor with the calculation we have before made on the data of Stavorinus. But, as will be noticed hereafter, there is reason to believe that numbers of the female trees just enumerated were old, although this is certainly but a small portion of the many adventitious and adverse circumstances which should ever be taken into an estimate of spice produce. It would be vain to attempt to reconcile on any other ground the discrepancy betwixt the quantity of produce per tree as determined from the account of Stavorinus, and that shewn by the Bencoolen Resident's statement.

It is believed too, that, while under the British, greater attention was paid to the cultivation of the trees than had before been bestowed on them, it would not be easy to account for the difference betwixt Major Thom's estimate and that of the Resident, of about 16,000 lbs. nutmegs as an increase. But it must be confessed that Stavorinus's account has not given all the details, because while he estimates the produce previous to 1778 at 350 lbs. of nutmegs it appears that in previous years 700,000 had been obtained.

It will however appear in the sequel that the produce has ever been subject to great fluctuations. These were owing to various causes, the most prominent of which were the eruptions of volcanos and earthquakes. We have seen that in 1778 a hurricane nearly annihilated the plantations—and in 1811 a severe storm destroyed much fruit. It has been also shewn from Hogendorp's account that eruptions of the volcano and devastating earthquakes have occurred at no very wide intervals—high winds frequently diminish the crops greatly. The trees were generally planted, perhaps to counteract this evil, too closely; being often only from 16 to 24 feet asunder; tall forest and other trees were

interspersed to arrest the force of the wind, the roots and shade of which must have interfered with the nutmeg trees. The latter are, it appears, only manured with the husks of the nut and fallen leaves. Sulphureous vapours sometimes blast the trees. Some of the hills even are more or less incrustated with sulphur. When old trees or others may have been cut down, their places may not have been always supplied at once by any excepting very young plants. The trees have their lower verticles so much pruned off that a rider on horse-back can easily pass under them. They also diminish in fertility after reaching a certain age, which of course must vary as to the locality and soil, but may be taken from 30 years upwards. But the nutmegs decrease in size and weight as the tree advances in age after a varying period.

Mr. Hopkins in 1812 estimated that, from that year up to 1824, the quantity of produce would be from six hundred to seven hundred thousand pounds of nutmegs from all the trees then planted out. Betwixt 1820 and 1826, an eruption of the volcano of Gunong Api at Banda demolished about three fourths of the trees. Since this catastrophe however there have been no serious inflictions either from wind or fire—so that perhaps the Bandas are now in as palmy a condition as they before were. Gunong Api throws out ashes and streams of sulphureous lava, thus rendering a large portion of the great Banda island useless for nutmeg cultivation. The flat land is not employed for this purpose.

The trees it may be supposed are subject to the same accidents and diseases that attack them in other localities, but I do not find these specified with the exception of the decay produced by white ants—which is always a very serious infliction.

The trees only *begin* to bear about the 8th or 9th year and before they have commenced to lose their shrubby aspect. So that until the tenth year has passed by, they yield but a small return. The nutmeg tree has been cultivated by the Dutch on the Bandas for two centuries and a half, and we can only attribute to its being in its indigenous position, the circumstance, that it has not long ago exhausted the soil, or that, according to the general laws which affect the growth of trees and plants, it has not become unfit at least for this peculiar kind of cultivation. It may nevertheless be assumed that inasmuch as cultivated produce almost always exceeds in quality that which is left to the sole care of nature, so the superior attention paid to the rearing of the nutmeg tree in the straits, where it is in a degree exotic, would seem to ensure a higher rate of productiveness to it than what is to be obtained from the Banda trees. But at the same time we shall have here to assign to this tree a shorter life than that to which it seems to attain in Banda.

## NUTMEG.

There are four chief sources from which the Dutch derive their nutmegs and mace for exportation. From the *Bandas*, *Celebes*, *Palembang* and *Bencoolen* in Sumatra and *Java*—but scantily from the latter island, and perhaps a few other but insignificant localities. But the proportion of the *Moluccas* or *Banda produce* to that of these other places, and which last is termed *free*, is nearly as 100 to 11. The free nuts are deemed a good deal inferior to the monopoly ones. The proportion of Nos. 1 and 2 of these so examined was found to be about one tenth, of any given quantity of mixed nuts.

The merchantable monopoly nuts and mace are sent to Europe and the inferior sorts are crushed and the oil is converted into *nutmeg-soap*, an article which has not yet perhaps been appreciated in England, but might possibly be converted to some useful purpose.

The cultivation of the nutmeg in Java is free, and several years (5 or 9) ago the number of trees then *planted out* was about 40,000. But as there are other safer and more quickly returning kinds of cultivation in that fine island, it does not appear that the nutmeg cultivation there is a favorite one with Europeans.

In 1816, which was eight years before Bencoolen was given up to the Dutch, it was reported officially by Lumsdaine that there were then at that station 26,049 bearing trees. The estimate for 1825 was an addition to these of 15,000 trees, making the total to be 41,049 and for the succeeding years the expected produce was rated at 128,000 lbs of nutmegs, besides mace. The above number of trees would afford us  $3\frac{1}{2}$  lbs of nutmegs for every good bearing tree, which is pretty near to the already noticed average in former years for Pulo Aye.

The total produce of that station at the present day does not it is believed exceed 30,000 lbs and may fall much short of this: 4,160 mace. Little attention seems to be paid to the trees and it was stated by persons who had been there several years ago that a worm had attacked the tree. An export duty of 10 per cent is said to be levied on the spices, which must have its effect in these days of low prices.

In returns obtained from England and other quarters and which correspond as to the quantities of produce with the one given in the January number of the journal, the produce of the eight years from 1828 to 1838 both inclusive, was an average of only 263,520 $\frac{1}{2}$  lbs English per annum of nutmegs, with the due proportion of mace, shewing that the volcanic eruption which happened not long before the first mentioned year, had been the true cause of the deficiency. The table of export of nutmegs from Java as appended in the Journal does not discriminate betwixt the monopoly and free nutmegs.

## NUTMEG.

The highest produce in nutmegs of any one year from 1825 to 1845 both inclusive, was 8,158 piculs, or lbs English 1,101,303, and the lowest 1,171 piculs or 158,085 lbs English, reckoning 135 English lbs per Dutch picul.

The average of the ten years ending in 1845 was 4636 Dutch piculs or 626,386 $\frac{1}{2}$  lbs English per annum, being 73,614 lbs at least less than the average of the Dutch writer Stavorinus for the middle or earlier part of the 17th century.

But this is not the average of the monopoly nutmegs alone. If we deduct from the above total per annum, the average produce annually of the free nuts from the various stations before named, including Bencoolen being on an average of eight years ending in 1857, 71,820 lbs English, we shall have the monopoly average reduced to 554,566 lbs English per annum.

It is highly improbable that under the present system any increase will take place over this quantity—for independently of it, the trees are we may suppose in their prime, more than 20 years having elapsed since the devastation caused by the last volcanic convulsion already described.

Of late years, as I have been assured, all the nutmegs of a fair merchantable quality have been sent direct to Holland—and the inferior sorts have been converted into nutmeg soap. It is not clearly shewn however where the line lies which cuts off these inferior nuts. It may be presumed that they include what in the Straits would be termed Nos. 5, 6 and 7 and refuse.

The medium sorts chiefly go to China, and to the Eastern Archipelago, as the Straits appear now to supply India.

In 1840-1, however, there were 47,250 lbs of nutmegs imported from Java into Singapore being nearly two-thirds of a year's produce of the nutmegs, on an average of these two years.

But let us admit that the annual average of monopoly nutmegs is 600,000 lbs, and that as the plantations are in their prime the number of bearing trees is the same as it was in the earlier and more flourishing period of the cultivation.

If then the 461,700 lbs nutmegs in 1814 were the produce of the original 691,500 female and monœcious trees but then reduced as before stated to 544,700 good bearing trees, there ought to be now in the *Bandas* in order to produce 554,566 lbs, the number of 363,799 good bearing trees. If we were to apply Dr. Oxley's scale for the Straits, and which allows 10 lbs of spice or say at the very least six lbs of nutmegs to every good bearing tree, the number of good bearing trees at the *Bandas* would, if equally productive, amount only to about or nearly about 100,000, a result which would never be admitted by the Dutch themselves and is quite at variance with all the authentic statistics which have yet appeared.

## NUTMEG.

To exhibit this part of the subject in a clear light let us revert to Pulo Aye. It contained 45,000 trees and yielded

130,000 lbs. nutmegs... .. 45,000

At this rate the two Bandas, which gave 530,000 lbs. of nutmegs, must have had, ... .. 183,46

Total of trees... 228,461

So that even at the highest Dutch rate of productiveness, or 4 lbs. per tree, after deducting 10 per cent for small trees, we should have had from the above total the quantity of 822,460 lbs. of nutmegs, instead of 533,950.

The number of good bearing nutmeg trees in Pinang and Province Wellesley has not been accurately ascertained, owing chiefly to the difficulty of getting correct returns from the Chinese growers. The returns obtained for 1844-5 shewed then upwards of fifty plantations having from 200 bearing female trees up to 12,000 besides 390 nutmeg gardens varying in their contents from 10 up to 200 bearing trees. The total of bearing female trees was upwards of 70,000. But a large increase has taken place since that year.

The actually exported produce for 1847-8 (vide Table) was 2070 piculs of nutmegs or 276,000 lbs. English: besides mace in the usual proportion, so that even admitting that no more female trees had come into bearing, which is very far from being the case, the general average of all the female trees in bearing will have been 500 good merchantable nuts, or a fraction more than  $3\frac{1}{2}$  lbs. per each full bearing tree, or 16th less than 4 lbs.

The table given by Dr. Oxley wants precision, inasmuch as he puts down "produce" without specifying its nature, whether all nutmegs or partly mace. If the mace is to be deducted, we should not have more for 1848 than 25,200 lbs. This he seems to infer since his number of nutmegs would hardly yield so many lbs. of good nutmegs and would probably fall short of it by 46 piculs at least. The bearing trees therefore cannot have yielded more than  $2\frac{1}{4}$  lbs and a trifling fractional part of a lb of sound nutmegs.

We have now therefore the following results:—

*Total Produce by the foregoing details.*

	Nutmegs lbs. English.	Mace lbs. English.	
The Moluccas and Free Trade at the highest.....	600,000	150,000	(a)
Pinang and Province Wellesley 1847-8.....	276,000	88,133	(b)
Singapore 1848.....	25,200	8,400	(c)
Total lbs. ....	901,200	246,533	...
Increase since the first part or middle of the eighteenth century.	651,200	146,500	

(a) This would be one-fourth part of mace.

(b) This would be  $\frac{1}{3}$ d nearly of mace.

(c) This at  $\frac{1}{4}$ th mace.

## NUTMEG.

The return of Pinang exports for 1848—9 cannot be obtained till May and June. An addition of some thousands of lbs would probably then be required to be made to the above quantity.

*Consumption.*—It would be difficult to exhibit correctly the average consumption of nutmegs and mace in the various quarters of the world. There are in fact but very partial data for a computation of it. However this may be, it might be reasonably concluded that all which is produced, is consumed—and that the fall of prices within the past 12 or 15 years has tended to increase consumption to the extent of the amount of increased produce which the extra Hollandic countries to the Eastward have yielded during that period, beyond that of the Dutch monopoly and free cultivation.

The tables appended to this paper and the "Statistics of Nutmegs" will shew where the produce goes from Java and Pinang. Dr. Oxley does not tell us how the Singapore nutmegs are disposed of. It appears that they are chiefly sent to Great Britain.

Little more than one half of the Pinang produce goes to England, or 140,266 lbs. If Crawford's estimate in 1803 of the consumption in Great Britain, or 56,960 lbs. of nutmegs, will apply to the present average rate of consumption there, then a large exportation must take place from that country.

The above author also estimated the consumption of mace in Great Britain at  $11\frac{1}{4}$  parts to 100 of nutmegs.

Unluckily for the planters the taste for these spices does not seem to have been improved by the fall of prices but approaches an inverse ratio. The devastating causes which occasionally reduced the quantity of produce in the Moluccas were unknown to the world, which supposed that consumption was greatly on the increase, because prices were high.

I shall now attempt to estimate the cost of originating and upholding a nutmeg plantation of 3,000 female trees up to the period when its receipts should balance its ordinary expences.

The value of land in Europe depends for the most part on what may be grown, not what actually is growing, upon it, and it has *per se* a real value which may continue with occasional fluctuations for centuries, may for thousands of years or longer. But in these regions, land, with the exception of rice land, has little or no permanent value and depends mainly for that which it has, on the trees or plants growing permanently upon it. Hence, whilst the grain grower would not be ruined by the destruction of a crop, the spice planter may be utterly so by a storm, an earthquake or any one of the catastrophes to which the earth's surface is liable.

## NUTMEG.

The charges attending the originating and upholding of a nutmeg plantation will vary, but not to any great extent, according to its locality, the nature of the soil and other extraneous circumstances, and like all tropical cultivation, its out-turn will depend a good deal on the price of labour.

The Resident of Bencoolen in a public report to the Supreme Government, dated 1816, describes the several items of expence in originating a plantation of 100 orlongs of land ( $133\frac{1}{2}$  acres) and upholding it till the tenth year. The number of trees in this case would not exceed 6,000 male and female, and ought to be less, if at 30 feet asunder.

Original cost of land, buildings,	Sp. Drs.
implements, labour, cattle, plants....	10,000
Annual charges at 6,395 Drs. for the	
next 8 years....	21,160

This will be up to the tenth year as the plants are set at the 2nd year of their age—and without calculating interest on the outlay. .... Sp. Drs.  
13,160

But he has failed to notice that at the end of these eight years, and we here follow Dr. Lumsdaine who was himself a planter, there would only be 3000 females for every thousand trees originally planted out, viz: that in every 1,000 plants, no more than 750 would reach maturity and only 300 of the latter would be females, which with 50 males to be *retained* would give 350 for the fixed cultivation, that is to say, out of the 6,000 planted out there would only be 1800 female trees. I apprehend however that if the plants were originally kept well apart in a nursery and carefully removed when from two to three feet high, and should the seed nuts have been carefully selected from the upper portions of the trees, there would be a fair probability of one-half turning out female trees.

But this infers the necessity of beginning anew the cultivation of the deficient 3,000 which again at the end of another eight years will demand a recourse to a similar process of renewal, so that the originally contemplated number of bearing trees cannot well be established until the 20th or 25th year at least, after the plantation was begun.

The cost of originating and cultivating a plantation at Pinang will fall short of those just detailed, which is owing to the cheapness of labour there compared with that of Bencoolen, and also to the improved mode of conducting the speculation, for such it must be called.

Dr. Oxley allows 70 trees to an acre, which is a rule quite at variance with the custom which has hitherto obtained in Pinang where 30 feet

## NUTMEG.

has always been considered the proper distance betwixt trees. So that instead of this large number we should only have 33 trees (■ nearly as possible) for each acre, not reckoning one acre by itself, but a number of acres in a square acre. This figure also of 2s 6d per lb. is opposed to the mercantile value in the English market for the past year at least, and far beyond the local market value, which should be the criterion—as all else is of mercantile speculation.

Dr. Lumsdaine, in his report on the Bencoolen plantations in 1816, says that he values the trees at  $3\frac{1}{2}$  lbs nutmegs each per annum. He allows about 420 lbs of merchantable produce for every 100 of full bearing trees at 15 years old, when he says they are at their highest rate of productiveness, but he adds that some trees yield large crops and others hardly any.

By accounts received from various plantations at Pinang and in Provinc Wellesley the general average results of produce appear to stand thus.

To give a picul by net of merchantable nutmegs in the shell requires nearly 14,819.

This was the average of three estates.

1st Estate .....	14,492
2nd do .....	15,473
3rd do .....	14,492
	44,457

The even quantity of 15,000 nutmegs of all kinds, yields on an average thus:—

	No. of Nuts.	No. of Nuts. per lb.
Of No. 1	1,335	72 to 73
No. 2	4,300	93
No. 3	3,750	111
No. 4	2,094	131
No. 5	1,840	
No. 6 and 7	bad, broken &c. 1,681	

but the weight differs a good deal during the several months of the year. In the dry months the fruit is light and inclined to shrivel.

The mace will be nearly  $37\frac{1}{2}$  lbs.

Or take 100,000 nutmegs in the shell unpicked. Then we shall have:—

No. 1 ... ..	87. 8 catties.
No. 2 ... ..	230.
No. 3 ... ..	167. 14
No. 4 ... ..	80.

With mace nearly as above.

The above quantity of 14,819 nutmegs to a picul is produced by  $29\frac{1}{2}$  trees at 500 nuts per tree.

## NUTMEG.

Crawford averages at 65 oz. avoirdupois of nuts and mace together per tree, which, deducting  $\frac{1}{4}$  for mace, will leave nearly 3 lbs of nutmegs for each bearing tree.

The weight of a given quantity of nutmegs in the shell to the same when freed from it is as 73 to 50 nearly. The mace may be assumed to be about  $3\frac{3}{5}$  (\*) of the whole. (Note. We presume  $\frac{1}{8}$  is meant.—Ed.)

The Dutch used to allow  $12\frac{1}{2}$  per cent loss in curing the nutmegs and mace and the loss afterwards by waste and accident at one third of the whole, which last however appears to be a very high estimate if confined to curing and transporting.

Out of 1,000 nutmegs the produce of any single tree, there will be only about 500 which will be of value.

The plantation has now reached the point when its produce ought to balance its ordinary expences.

Dr. Oxley (Journal Ind. Arch. Vol. 11 p. 657.) observes that good trees yield 10 lbs of SPICE after the 15th year.

This doubtless included mace, and if so the produce in nutmegs would be after a deduction of  $\frac{1}{4}$  for mace,  $8\frac{1}{2}$  lbs per female tree. But the Editor of the Pinang Gazette (25th November 1848.) has controverted this statement.

Dr. Oxley's own Table of Produce shews for his own estate 2,322 bearing trees, and a produce for 1848 of 902,426 nutmegs—thus making only  $388\frac{1}{2}$  per tree. This last number, at the average calculation already stated above, would, throwing the  $\frac{1}{2}$  out, only allow of 3 lbs and a small fractional part of a lb per tree. This estimate of actual produce will therefore admit, for his whole plantation of 2,322 bearing trees, the quantity of  $6,966\frac{1}{2}$  lbs of nutmegs—which are about 290 lbs more than are set down in his column of "produce weight."

But if we take the whole produce of all the plantations noted in his Tabular statement, the result is 14,914 bearing trees with a produce in numbers of 4,085,861 nutmegs—only 273 and nearly  $\frac{3}{4}$  nuts per tree, which make very nearly  $2\frac{7}{8}$  lbs. per tree of nutmegs and  $\frac{1}{4}$  of that quantity of mace.\*

\* Colonel Low appears to have overlooked the column of "Remarks" in Dr. Oxley's paper, in which it is stated that "the greater number of the trees in Singapore, as will be observed from this table, have not come into full bearing, but the produce is increasing rapidly and this year (1848) will amount to fully 500 piculs."—Ed.

There is an abstract of the nature of the produce of three Nutmeg estates in the colony of Pinang, including Province Wellesley.

## NUTMEG.

15,000 nutmegs which had undergone the process of drying and which rattled in the shell

† Planters do not always adhere to a given size in assorting No. 1, and when the season is adverse or during the least productive months in the year, No. 2 becomes No. 1, or at least the quantity of the true No. 1 is too small to be worth much notice.

The produce for these three estates we have already mentioned. The annual produce therefore of the 2,000 trees alluded to in the estimate, after they have reached a good state of bearing would probably be, at 500 nuts per tree, 8,000 lbs, or 60 piculs. I have before rated the produce per tree at  $3\frac{7}{8}$  lb. but it is by this estimate about 4 lbs. It should however be remembered, as before stated, that the weight of nutmeg fluctuates much during a year—being at its maximum during the rains and at its minimum in the very dry months.

This table allows an average of about 111 or somewhat more, perhaps 112, nuts per lb. of all sorts indiscriminately—say 111 so that 100,000 ungarbled and unselected nuts, after being liberated from the shell, would yield 900 lbs of all kinds of nuts and  $\frac{1}{4}$  more or less of mace at the above estimate, but varying a little throughout the year.

The present local prices rule upon an average 1s. 9d. per lb. for sound nuts. So that the total produce value obtained on the spot would be 4,000 Spanish dollars, reckoning 400 cents of a dollar per 1,000 nuts. The mercantile value is quite uncertain, being a speculative one, but with reference to late prices it cannot be rated much higher than the above price. The future, it must be confessed, is any thing but cheering to planters, for while they cannot reduce expences below a certain point, without great danger to their estates, the prices of nutmegs have every prospect of continuing to fall in the same ratio as they have done for years past. Under this view, as the quantity of nutmegs increases, by the natural progress of the trees to maturity, the ex-

## NUTMEG.

pected increasing profit becomes neutralized by the decadence in its market value.

With advertance to the cost of cultivating nutmegs in the Bandas, Mr. Crawford has stated it at 8 dollars the picul. If it had been found practicable by the Dutch to raise the nutmeg at so low a figure, all competition with them would have been at an end. It is likely that when foreigners first resorted to these islands they obtained only the nutmegs which the woods afforded, as no cultivation had begun until a period long subsequent to their advent.

It may be premised that the Moluccas possess no other produce in such quantity of sufficient consequence to attract trade, and that the nation which holds them must tack on to the cost of raising the tree that of protecting these islands.

Let us again take as our guide, the Dutch author Stavorinus, who informs us that the civil and political charges for upholding the Bandas were in his time £12,000 sterling (calculated from Dutch money) To which was then added the sum of £14,000, paid to the cultivators for nutmegs and mace, making £34,000, by *these two items alone*, so that until the plantations had been renewed eight or nine years after the hurricane, the nutmegs and mace together must have borne a very high prime cost, for the whole expences of these unproductive years must have been charged against them. In like manner such a serious contingent as an earthquake and an eruption or hurricane should be considered in all prospective estimates of produce in these localities.

The Dutch Government in these times supplied slaves and convicts to the cultivators with rice for them at 90 guilders per coyan, although it cost them originally 180 a 200 guilders per coyan.

Martin acquaints us that when he was Resident at Amboyna there were 2,160 slaves in the plantation.

Slaves are, it is believed, paid in some shape or other by the cultivator or cultivators, and the convicts are paid by the latter at 2 copper guilders per month—with 40 lbs. of rice and two suits of clothes yearly. There is no free labour here.

The Government purchases the spices from these contractors at the following rates:—

Cents of a dollar.

Nutmegs 1st quality per lb .....20

Do. 2nd do.....15

Mace.....25

The cost of 900 tons from the Bandas and Amboyna to Java, previous to that of transporting the spices to Europe, requires also to be added.

A force, it is believed, is kept up as in former times to prevent smuggling, which comes however under the head of Government charges in the civil and military departments.

## NUTTALLIA GRANDIFLORA.

The Military force kept up is from 300 to 400 men, one half of them European, the rest natives.

Were the Dutch to abandon these islands, the natives would cultivate the spices themselves. But we might readily predict that in such an event the same care would not be taken of them, for they would not be readily supplied with slaves and protection, and the natives might fall into anarchy when left to rival chiefs. But there seems to be no intention of giving up these islands, at least while they can be made to cover their expences—for this would leave a portion of the Dutch Archipelagic empire open to intruders.

When this sketch was nearly finished the account of Count Hogendorp came opportunely to hand—but unfortunately it comes no higher up than 1822. This abstract of the whole stands as under:—

## O.

(2034) OOLOGY, *Indian Oology—Notes on the Nidification of some of the commoner birds of the Salt Range, with a few additional from Kashmir, by W. THEOBALDS, Junr., Esq.*

The present paper is the result of observations made during the years 1852-3, chiefly in the neighbourhood of Pind Dādan Khān and Katas, in the Salt Range, with a few scanty, notes made during a flying trip of a month to Kashmir.

The only paper on the same subject was one by Captain Tickell, with which in one or two instances these notes will be found to differ. Layard and Kelaart have also given brief notices on the same subject from which one curious fact may be deduced, viz that the same birds nest varies at times in different parts of the country, a fact by no means surprising when the great extent and varied physical, seasonal and climatic features of our Indian empire are taken into consideration.

At present however, we must content ourselves with the careful exploration of particular districts without attempting to follow out the laws which doubtless regulate these seeming anomalies, which would require much more extensive information than we are at present possessed of.

It is not easy to explain why Oology has not found more favour with those whose taste or opportunities incline them to cultivate some of the minor branches of natural science, for without any undue bias it may at least be reckoned as entertaining and instructive as many of those "ologies" which are usually considered pleasing, and withal, not unfashionable. Many however, who are ready enough conventionally to tolerate other similar pursuits, can, without being able to assign any particular reason, see in Oology little else than trifling and loss of time,

but it requires very little examination to upset such an estimate, for there are few similar studies, if any, that surpass it in interest, few more varied, and none offering a less worked field of enquiry and speculation.

What varied and touching instances of craft and devotion does not the maternal *στοργή* prompt for the concealment and preservation of the callow brood either from natural enemies or from unforeseen perils, and where can we look for more pleasing instances of self denial than among birds engaged in tending their eggs or young. This has ever been a favourite and admired subject with poets and lovers of nature, who will not fail to accept in a far wider sense, than originally attached to them, the lines of Flaccus.

"Non ferox

Hector vorax Deiphobus graves

Excepit ictus pro pudicis

Conjugibus puerisque primus."

At no time too, are more conclusive proofs displayed by the brute creation of intellectual power, than by birds engaged in the duties of incubation. It appears indeed little less than absurd and mere prejudice, to deny this faculty to the inferior animals, for if reason be defined in terms, their actions in a greater or less degree will be found to fulfil those terms with those of man himself, without doubt unmeasurably the highest in every respect of living forms, but between whom and the humbler inhabitants of the earth, that absolute gulph does not exist which his pride—his reasoning pride—has induced him to surmise.

The strong sense of Milton did not fail to see and acknowledge this, for Eve addressing the serpent, says;—

"What may this mean? language of man pronounced?"

By tongue of brute, and *human sense* expressed :  
The first at last of these I thought denied  
To beasts, whom God on their creation day  
Created mute to all articulate sound  
The latter I demur, for in their looks  
Much *reason*, and in their actions, oft appears."

This passage shewing an acquaintance with, and appreciation of, the habits of animals, far from common at the time he wrote, affords a pleasing insight into the character of our great poet.

The means found best, for preserving the fragile objects under consideration, may prove of some service to other collectors.

There are three ways which may be adopted for emptying an egg according to its size and the amount of incubation it has received. All eggs when fresh or only slightly incubated may be blown after a manner, we shall now describe, but some care and careful handling are required to succeed with such eggs as of the English wren or Indian palmswift. The ordinary mode which the young idea usually aspires to inculcate into grandmama is to make a hole at *both* ends, but after deciding on the proper spot which is best in the side, an oval hole must be made varying with the size of the egg, and on holding the hole downwards the contents are easily evacuated by blowing into the egg through a fine pointed blow pipe, the tip of which is just introduced within the shell.

The operation is neat and effectual but a violent blast must not be attempted, as in that case the yolk, may cause a momentary obstruction and the egg explode from the pressure of the confined air within. Neither should the hole be made too large, as the air will then find too ready an exit and fail to expel the last portion of the contents. The empty shell should then be immersed in water and filled, by first exhausting the air with the blow pipe, this will effectually clean the interior, and the last remains of moisture may be absorbed on blotting paper. The interior should then be washed with a solution of corrosive sublimate in spirits. A common six-penny brass blow pipe answers perfectly for this.

When, however, the incubation has lasted a long time, a good plan is to extract the contents by means of a pin bent into a hook. This is a tedious operation which we merely mention in case of any rare egg requiring to be so treated. A third plan answers well for all eggs of a large or medium size, when well incubated. A moderately sized hole must be made in the eggs and the more liquid portion of the contents got rid of. They should then be wiped clean and placed in a shallow pan, when in a few days the maggots of the flesh-fly will consume the contents. They will then only require to be washed; The best mode of packing moderate sized eggs in store is in wooden boxes with saw dust, after closing the holes in the shells with their paper.

Tin boxes are not generally to be trusted, at least when travelling, as with such tender charges committed to their care a little smash goes a great way, as he has ruefully learned from experience. Small eggs travel well packed in some soft nests as those of "*Lanius*" with a little wool and placed in wooden boxes. Small tin boxes fitted into trays in a wooden box are also very handy, but are not readily got well made in India.

For the nomenclature adopted in the present paper the writer was indebted to Mr. Blyth, in several cases from the examination of skins of birds shot off the nest, and with a few exceptions, no reasonable doubt attaches to the correct identification of any bird in the present paper; those to which any uncertainty attaches are indicated by asterisks.

The *Local Name* is ranged under the specific in the second column, the next contains the *Month* and *Week* in which the eggs are laid; the last column the colour of the eggs and a description of the nest.

In the penultimate column, three heads are contained: The number of eggs; usually ascertained from well incubated eggs, to guard against error. The form of the eggs expressed by letters; and the measurement of the long and short axes in inches and decimals of an inch. The following are the commoner forms in the abbreviations used.

(2066) *Malacocercus Caudatus*, Sor. March, April, May, June, August.  
4-5 O. P. L. O. P.  $\frac{0.84}{0.66} \frac{1.04}{0.60} \frac{0.75}{0.55}$

Clear greenish blue. Nest a loose but deep cup of grass and twigs in bushes in jungle or garden. The first size is common, the second and third measurements were from eggs of one nest.

(2067) *Oxylophus melanoleucus*. (Identified by Mr. Blyth) August.  
1. B. O.  $\frac{0.61}{0.81}$

Deep greenish blue. This evidently parasitical egg was taken from the nest of *Malacocercus caudatus* containing four ordinary eggs which it closely resembles in colour, though its form indicates its parasitical character.

(2068) *Galerida cristata*, Chandul. March 4th, May 3d.  
4. O. P.  $\frac{0.88}{0.66} \frac{0.82}{0.64}$

Yellowish white uniformly freckled, with grayish yellow and neutral, Nest, a little grass in a hole in the ground.

(2069) *Thamnolia Cambaensis*, Jimma (generic) April 2nd.  
4 P. O. P.  $\frac{0.79}{0.60}$

Greenish white ringed and spotted with pale reddish and a little neutral. Nest, loose grass and bits of snake's skin in holes in the sides of nullas.

(2070) *Nectarina asiatica*, May 4th.  
O. P.  $\frac{0.66}{0.47}$

Grayish white, freckled and ringed with cineritious gray. Nest, a neat purse of vegetable fibre and down suspended from some small bough and masked in front by a few dead leaves loosely attached by silk threads.

(2071) *Munia Malabarica*, May, August, September, October, December.  
12.13=(25) O. P.  $\frac{0.59}{0.46} \frac{0.64}{0.44} \frac{0.60}{0.50}$

Pure white. Two pairs of birds frequently if not usually are employed in the construction

of one nest in which the two hens consecutively lay—so the same nest has sometimes 25 eggs in it in different stages of incubation—nest often clumsy and hastily made—but usually a neat domed structure of fine grass with one opening, sometimes prolonged into a short deflected neck partially closed by the elasticity of the long spikes of grass forming it; sometimes the nest is a simple platform of grass, open at each end, but the grass ends curved over to meet at the top, usually placed in thorny bushes, often very conspicuously and close to roads. It is much to be doubted if the eggs found occasionally in October and December are hatched.

(2072) *Podiceps Philippensis*, Pandubi. August, September,

5. P. O. L. P. O.  $\frac{1.50}{1.04}$   $\frac{1.42}{1.00}$

Pure white; when recently laid, green: is soon soiled brown in the nest. Nest, a few weeds heaped on the rank vegetation of jheels, but floating and usually several nests together.

(2073) *Gallinula chloropus*, August 4th,  
O. P.  $\frac{1.62}{1.15}$

Pinkish cream or gray spotted and slightly ringed with deep red brown.

(2074) *Sarciophorus bilobus*. Jithiri. May 2nd.

3. P.=O. P.  $\frac{1.63}{1.19}$

Nest as *Podiceps philippensis* eggs also stained by nest; creamy yellow or stone colour, thickly spotted and blotched with blackish brown.

(2075) *Ardeola leucoptera*. Bogla (generic.) June 4th.

5. 6. P. O.  $\frac{1.54}{1.16}$

Pale green. Nest of loose sticks in trees.

*Kashmir Notes.*

(2076) *Tinunculus alandanus*. Shikra. April 3rd.

6. B. O. P.  $\frac{1.68}{1.22}$   $\frac{1.51}{1.27}$

Pale reddish brown, freckled and blotched with brownish red. Nest, hole in sarai wall of Thanna S. of Baranegala Shahabad and valley generally.

(2077) *Milvus*? *Buteo*, April 4th.

2 O. P.  $\frac{2.10}{1.80}$   $\frac{2.40}{1.77}$

Nest and eggs as in plains (*Buteo canescens* ante).

(2078) *Corvus*, Small black hill Crow. April 3rd.

4. O. P.  $\frac{1.70}{1.20}$   $\frac{1.60}{1.25}$

Green spotted with brown, valley generally. Nest placed in "Chinar" and difficult trees.

(2079) *Corvus monedula*, May 1st.

4. 5. 6. O. P. L. O. P.  $\frac{1.26}{0.99}$   $\frac{1.45}{1.00}$   $\frac{1.60}{1.00}$

Pale clear bluish green; dotted and spotted with brownish black. Valley generally; in holes of rocks, beneath roofs, and in tall trees.

(2080) *Sturnus vulgaris*, Jilgiri. May 2nd, 3rd.

O. P.  $\frac{1.15}{0.85}$

Pale clear bluish green. Valley generally; in holes of bridges, tall trees, &c. in company with *Corvus monedula*.

(2081) *Acridotheres tristis*, April 3rd.

Nest and eggs as in plains Rajaori and lower hills generally.

(2082) *Cacabis chukor*. May 3rd.

Nasmana on the Chandra-baga: eggs as ante.

(2083) *Pycnonotus leucotis*, April 4th at Bhimba. May 2nd at Islamabad.

Nest and eggs as in plains ante No. 23.

(2084) *Hirundo rustica*, \* May 2d  
4. L. O. P.  $\frac{0.83}{0.53}$

Pure white, spotted with bright reddish brown; valley generally. Nest under eaves, outside course straw cemented with mud, inside fine straw lined with feathers.

(2085) *Budytes citreola*, May 3d.

4. O. P.  $\frac{0.95}{0.70}$

Pale gray thickly dotted and ringed with grayish brown and grayish neutral mingled together. A depression in soft earth beneath a rock near B'aragari, valley generally.

(2086) *Anas Boschas*, May 1st.

L. O. P.  $\frac{2.27}{1.55}$

Dirty white with a tinge of yellowish green near Supeia, valley of Cashmir.

(2087) *Podiceps cristatus*? May 2d.

5. O. P.  $\frac{2.53}{1.51}$

Pure white; when recently laid pale green. Wala lake Nest, a heap of weeds floating on the surface of the water, but connected to reeds, &c.

(2088) *Podiceps Philippensis*, May 2d.

5. P. O.  $\frac{1.40}{1.00}$

Pure white. Wala lake. Nest as *Podiceps Cristatus*.

(2089) *Fulica atra*, May 2d.

8. L. O. P.  $\frac{2.10}{1.40}$

Pale brownish gray, dotted with reddish black. Wala lake. Nest, pieces of dried reeds

about 6 inches long, piled together among reed and floating on the water.

(2090) *Gallinula chloropus* May 2d.

O. P.  $\frac{1.70}{1.26}$   $\frac{1.57}{1.11}$

Pale gray or reddish gray dotted and spotted with deep reddish brown. Nest, a few weeds heaped on the water among reeds.

(2091) *Eudynamys orientalis*; Monghyr, June 3d.

1. O. P.  $\frac{1.20}{0.90}$

Pale dirty green, much blotched with reddish brown. Had but one egg brought, and the man reported four crow's eggs in the same nest.

(2092) *Centropus rufipennis*, Monghyr, June, August.

4. O.  $\frac{1.30}{1.09}$   $\frac{1.47}{1.21}$

Pure white: nest placed in dense trees, a neat but loose structure of twigs domed, and with aperture in the side lined with dried leaves.

(2093) *Cypselus affinis*, Monghyr, May, June.

4. O. P.  $\frac{0.90}{0.66}$

Pure white; nest described in a former paper. Mr. Layard, however, describes it as building a *mud* nest in Ceylon (vide annals for 1853, page 311).

(2094) *Milvus ater*, Calcutta, October 4th.

3. O. P.  $\frac{2.21}{1.68}$

Greenish-white, spotted and blotched with pale reddish brown: nest of sticks, bulky, placed in tall trees.

(2095) *Gyps bengalensis*, near Deoghur, November 4th.

1. O. P.  $\frac{3.20}{2.52}$

Pure white. Nest of sticks, usually small for the size of the bird, and placed at the top of cotton trees or others, very difficult to ascend.

(2096) *Buceros cavatus*. Tenasserim, February 3d.

1. O. P.  $\frac{2.68}{1.88}$

Pure white. For the measurement of an egg, indebted to Capt. Tickell, who was fortunate enough to observe the female on the nest.

In holes of trees, in which the female is built in with mud by the male, as observed by Capt. Tickell (p. 279, *ante*).

(2097) *Buceros subruficollis*, Tenasserim, February 3rd.

3. O. P.  $\frac{2.20}{1.55}$

Pure white. Mode of incubation said to be similar to the last.

(2098) *Halcyon smyrnensis*, Mergui, March 4th.

5. B. O.  $\frac{1.20}{1.03}$

Pure white. Gallery  $1\frac{1}{2}$  feet in a stiff bank, near a road.

(2099) *Halcyon gural*, Monghyr, June 4th.

4. R.  $\frac{1.09}{1.02}$

Pure white. Gallery 1 foot in a stiff bank, in jungle.

(2100) *Merops erythrocephalus*, Mergui, March 3rd.

5. 6. P. O.  $\frac{0.84}{0.79}$

Pure white. Gallery from 1 to 7 feet in length, in soft sandy soil near water. It enters the ground at a small angle and then runs horizontally.

(2101) *Eudynamys orientalis*; Monghyr, June 3d.

1. O. P.  $\frac{1.20}{0.90}$

Pale dirty green much blotched with reddish brown. Had but one egg brought, and the man reported four crow's eggs in the same nest.

(2102) *Centropus rufipennis*, Monghyr, "Mahoka" "Karmowa" June, August.

4 O.  $\frac{1.30}{1.09}$   $\frac{1.47}{1.21}$

Pure white: nest placed in dense trees, a neat but loose structure of twigs domed, and with aperture in the side: lined with dried leaves.

(2103) *Cypselus affinis*, Monghyr, May June.

4. O. P.  $\frac{0.90}{0.56}$

Pure white; nest described in a former paper. Mr. Layard, however, describes it as building a *mud* nest in Ceylon (vide annals for 1853, page 311).

(2104) *Cypselus balasiensis*, Monghyr, June 3rd, Prome, July.

3. L. P.  $\frac{0.80}{0.45}$

Pure white. Nest of vegetable down, with a few feathers agglutinated with mucus to the frond of the *Borassus*.

(2105) *Corvus culminatus*, Tenasserim, February 3rd. Near Deoghur, March 4th.

O. P.  $\frac{1.66}{1.15}$

Dull sap green, much blotched with brown. Nest carefully placed in tall trees.

# OOLOGY.

(2106) *Acridotheres tristis*, Monghyr, June, 1st. Prome, July 3rd (2nd brood.)

5. O. P.  $\frac{1.20}{0.85}$

Pale green. Nest in trees or holes in houses of grass and rubbish.

(2107) *Sturnus contra*, Monghyr, May 3rd, June 3rd, Tavoy, April 1st.

5. O. P.  $\frac{1.10}{0.82}$

Clear pale green. Nest of grass and twigs in trees.

(2108) *Malacocercus bengalensis*, Monghyr, June 2nd. "Fat-gobria," "Gogoi,"

5. B. O. P.  $\frac{1.00}{0.79}$

Deep bluish green. Nest of twigs and fibres in bushes.

(2109) *Malacocercus caudatus*, Monghyr, June, July.

4. 5 O. P.

Nest and eggs, previously described.

(2110) *Neornis flavolivacea*, Darjiling, July 2nd.

3. B. O. P.  $\frac{0.9}{0.55}$

Deep dull claret red, with a darker band at broad end. Nest, a deep cup, outside of bamboo leaves, inside fine vegetable fibres, lined with feathers.

(2111) *Orthotomus longicauda*, Darjiling, August 4th, Tavoy, May 1st.

4. O. P.  $\frac{0.61}{0.45}$

Greenish white, dotted with pale reddish. Nest, a neat cup of fibre and vegetable down enclosed in a single leaf, which is secured by stitches of fibre; so as to envelope its entrance at the top and beneath the stalk, the leaf serving as an admirable pent roof to the nest.

(2112) *Thamnobia Cambaiensis*, Monghyr, April 2d, June 3rd.

3. 4. O. P.  $\frac{0.64}{0.64}$

Greenish white, ringed and spotted with pale reddish, with some spots of neutral. Nest rude in holes, in trees and banks, of grass and nearly always snake skin.

(2113) *Hirundo domicola*, Tenasserim, April 2nd.

3. L. O. P.  $\frac{3.77}{0.52}$

White, spotted and ringed with umber. Nest a saucer of mud, inner part coarse roots, profusely lined with feathers, and vegetable down, attached to the under part of "Snags" projecting some 4 feet above the water.

# OOLOGY.

(2114) *Hirundo sinensis*; Salween R., January 2nd.

4. O. P.  $\frac{0.62}{0.48}$

Pure white. Nest of grass and lined with feathers.

(2115) *Pycnonotus hæmorrhous*; Monghyr, June 4th.

3. O. P.  $\frac{0.90}{0.68}$

Nest and eggs like *P. bengalensis*, previously described; eggs not quite so highly coloured.

(2116) *Nectarinia flammaxillaris*; Tavoy, February 1st.

2. O. P.  $\frac{0.56}{0.43}$

Pale greenish, speckled with greyish ash. Nest, a neat purse, in a lime tree (*Citrus*), like *N. asiatica*.

(2117) *Macrophygia leptogrammica*; Darjiling, July 2d.

O.—(1?)  $\frac{1.40}{0.98}$

Dirty white; nest, a few sticks.

(2118) *Fraulinus sinensis*; var. *Phayrei*; Burmah, June 4th (Miateh)

4. R. P.  $\frac{1.40}{1.15}$

Uniform greenish cream; on the ground.

(2119) *Turnix Ocellatus*, Monghyr, June 1st.

4. R. P.  $\frac{0.88}{0.74}$

Yellowish grey, closely freckled with dark yellowish grey, blotched with deep reddish umber with a few dots of neutral: on ground.

(2120) *Glareola lactea*, Tenasserim, March 3d.

B. P. (3?)  $\frac{1.01}{0.81}$

Dusky buff, ringed and spotted with obscure neutral and irregularly lined with yellowish brown. On churs and river sand banks.

(2121) *Ædicnemus crepitans*, Deoghur, April 1st.

2. O. P.  $\frac{1.80}{1.35}$

Pale stone-colour or yellowish cream, blotched with deep red brown. On ground in sal jungle.

(2122) *Hoplopterus ventralis*, Tenasserim, March 3d.

3. P.  $\frac{1.60}{1.17}$

Yellowish stone-colour or creamy nankeen, regularly spotted with deep red brown and sparingly blotched with neutral. On sand-banks in the river.

(2123) *Metopodius indicus*, Monghyr, August.

L. O. P.  $\frac{1.50}{0.97}$

# OOLOGY.

Clear brownish-ochre, strongly lined and streaked with black. Nest of weeds in jheels.

(2124) *Hydrophasianus chirurgus*, Monghyr, August 2nd,

4. P.  $\frac{1.33}{1.10}$

Clear brownish or greenish bronze: nest, weeds in jheels.

(2125) *Ciconia leucocephala*, Deoghur, June 4th.

3. P. O.  $\frac{2.50}{1.90}$

Dull white: nest of sticks placed in tall trees, usually "simul," most difficult to ascend.

(2126) *Herodias intermedia*, Monghyr, July 1st, 2nd.

6. O. P.  $\frac{1.76}{1.26} \frac{1.94}{1.30}$

Dull green. Nest small, of sticks; in company with "Mainas" and *Herodias bubulcus* and *H. garzetta*.

(2127) *Herodias garzetta* Monghyr, July 1st.

6. O. P.  $\frac{1.45}{1.14} \frac{1.58}{1.11}$

Dull green. Nest as *H. intermedia*.

(2128) *Herodias bubulcus*, Monghyr, June 1st.

6. 8. P. O.  $\frac{1.80}{1.39}$

Very pale green or greenish-white. Nest as *H. intermedia*.

(2129) *Porzana phænicura*; Monghyr, August 1st.

7. L. O. P.  $\frac{1.70}{1.10}$

Dark brownish cream, much spotted and blotched with brownish red. Nest of weeds in jheels.

(2130) *Gallinula Burnessii*, Salt Range, August 4th.

$\frac{1.62}{1.15}$

Pinkish cream or grey, spotted and ringed with deep red brown. Nest of weeds in jheels.

(2131) *Dendrocygna awsuree*, Monghyr, August 1st.

8. O. P.  $\frac{1.81}{1.50}$

Creamy white, nest of weeds in jheels.

(2132) *Nettapus coromandelianus*, Monghyr, August.

O.  $\frac{1.47}{1.10}$

Pure white, shell very thin.

The nomenclature used above is derived from the valuable catalogue of birds in the Museum

# ORANG-UTAN.

of the Asiatic Society, by Mr. Blyth; a work of great labour, which reflects the utmost credit on its author.)—*Beng. As. Soc. Jour. Jan. Oct. 1855.*

(2133) *OPHELIA ELEGANS*,

(Wight) Ic. Pl. Ind. Or. t. 1331. Erect, ramous above, obsoletely 4 sided. leaves sessile, narrow, ovate, lanceolate tapering to a slender point, 5 nerved; lateral nerves close to the margin: branches ascending, slender, bearing at each joint lateral, few flowered cymes, forming together a large many-flowered leafy panicle: calyx lobes narrow, lanceolate, acute, about two-thirds the length of the corolla: lobes of the corolla obovate cuspidate: foveæ bound with longish coarse: hairs flowers pale blue.

Pulney Hills, flowering August and September. A very handsome species when in flower, forming as it does, a rich panicle of light blue flowers streaked with deeper coloured veins. It seems very distinct from all the other species.—(Wight).

This plant grows plentifully in the Jeypoor Zemindary of Vizagapatam, and is largely exported as "Silaras" or "Selagit," the amount being valued at about rupees 2,500 a year. It is preferred by the hukeems to the genuine Himalayan Chiretta, and is considered febrifuge. (Honorable W. Elliot in literis).

The drug as exported, in bundles about 16 inches long, and 4 inches deep, and is always tied up with the tough bark and large leaves of *Bauhinia Vahlia*; (W and A.) which abounds in the Northern Circars.

Therapeutic Action.—Equal quantities of the *Exacum bicolor*, *Ophelia elegans* and of the *Chiretta* of the medical stores (which on examination was found to contain some stalks of the *Ophelia elegans*) having been infused, in the usual manner, (2 oz. to 1 pint,) four competent parties were requested to give their opinion on the respective qualities of the infusions. The result was the unanimous opinion that the cold infusions of *Exacum bicolor*, although a pure bitter, was much milder than that of *Ophelia elegans*, which possesses a powerful bitterness, remaining for several minutes in the mouth. Frequent trials confirm the belief that it exercises a tonic influence on the digestive organs, thereby improving the general health, while it appears also to have a febrifuge property.

(2134) *ORANG-UTAN*. Or remarks on the different species of *Orang-utan*.—By EDWARD BLYTH.

The Bengal Asiatic Society's museum received from Sir James Brooke of Sarawak seven skeletons of large adult *Orang-utans* and the results of Mr Blyth's examination of them, were given as a sequel to his former memoir on the genus published in the 22nd volume of the Society's Journal.

Of these seven skeletons, five are referable to the *Mias Rambli* of Sir J. Brooke; although

one of them (a small but full grown female) is marked by himself *M. Pappan*; and another is sent by the new name *M. Chapin*, which is also that of an old female animal, remarkable for its extraordinarily large and vertically elongated orbits. It is probable that this alleged *Chapin* merely represents an individual variation; and Sir J. Brooke states, in his letter announcing the presentation, that some of these skeletons had been labelled by him with the names specified by Natives, who, accordingly (as may be supposed in such a case), are not particularly conversant with the osteological distinctions of the different species.

The sixth skeleton is that of an old female of the *Mias Pappan*, with double-crested skull like that of the male figured in illustration of his former memoir. It even exceeds that male in size, but the skull is smaller; and the sexual distinctions of the two are unmistakeable. In this female, the epiphyses of the limb-bones, *scapulae*, *ilia*, &c. are thoroughly anchylosed, denoting completion of growth; even the *symphysis pubis* is united (with much irregular deposition of bone externally), and the sacro-iliac symphysis on the right side only. In no other of our orang skeletons are the two latter symphyses united. Our male *Pappan* had not quite completed his growth; for some of the epiphyses are loose, and others are but partially soldered: those of the *humeri* are fixed and semi-anchylosed; as are also those of the left *radius* and *ulna*; but the epiphyses of the right *radius* and *ulna* are detached; those of the *scapulae* and *ilia* are fixed but slightly, and those of the *ischia* more extensively. This animal had therefore (as will be attempted to be shown presently) not completed its full growth: the female being much more advanced in age, with its teeth proportionally worn down. On comparison of the skulls of the two sexes, that of the female is seen to be smaller, with the maxillæ less protruded, increasing the facial angle from  $32^{\circ}$  to  $35^{\circ}$ ; the zygomatic arch is much less robust; and the longitudinal grinding surface of the upper molars less by  $\frac{3}{16}$  in., while that of the lower molars is less by  $\frac{1}{4}$  in. than in the youthful male presented by Mr. Nicholls, and by  $\frac{7}{16}$  in. than in Dr. Clarke Abel's Sumatran male. In the form of the ascending ramus of the lower jaw, this female specimen more nearly resembles the Sumatran male referred to than any other of our numerous specimens; but the condyle is considerably larger; and, as compared with Mr. Nicholl's Bornean male, the antero-posterior diameter of the ascending angle is much less; being in the Bornean male (on a level with the surface of the grinders)  $2\frac{5}{8}$  in.,—in Abel's Sumatran male but  $2\frac{1}{4}$  in.,—and in Sir J. Brooke's Bornean female  $2\frac{1}{2}$  in. Lastly, this Bornean female presents the very extraordinary anomaly (throughout the series of placental main-

malia) of a fourth true molar above and below, though on the left side only: that of the upper jaw being of small size and round form, its crown scarcely exceeding that of an upper false molar of *Macacus rhesus*; and it is placed posteriorly to the ordinary last true molar on a line with its outer surface, that tooth having been pressed a little inward: in the lower jaw the accessory fourth true molar is very little smaller than the normal molars; and it projects from the internal margin of the anterior surface of the ascending angle of the jaw, its crown being directed obliquely inwards much more than forwards or upwards: as a functional tooth, it must, therefore, have been almost useless; though the outer or upper margin of its crown is a little worn down by attrition, as is also the outer cusp of the small accessory molar above. This old female *Pappan* had been badly wounded in its day; having had its left humerus severely fractured, and the fibula of that side also broken; the fractured bones having healed; the unset humerus, however, in an extraordinary manner, exhibiting two large and deep perforations in the great lumpy mass of united bone, where suppuration had ensued, and large shot had probably been ultimately discharged from the orifices.

The seventh skeleton is that of a species altogether distinct and new! Although that of a large old male, with the cranial sutures much obliterated, and the anchylosis of the epiphyses of its limb-bones complete, it is very remarkable for the comparatively slight protrusion of the jaws, and the consequently increased facial angle; apparently, however, to a greater extent than really, from the flatness of the face, the unusually slight protrusion of the sockets of the upper incisors, and, above all, the elevation of the condyle of the lower jaw raising so considerably the occipital portion of the skull and consequently the auditory orifice. The facial angle does not actually exceed  $32\frac{1}{2}^{\circ}$ ; while in the two *Rambis* (male and female) figured in my (Mr. Blyth's) former memoir, it is as low as  $30^{\circ}$ —(this being also Prof. Owen's estimate of his adult skulls of the *Rambi*). The *zygomata* (or cheek-bones) are unusually prominent. The canines, incisors, and the first three upper molars on each side, are exceedingly much worn down by attrition; the canines even to a level with the other teeth; but the circumference of these canines, especially in the lower jaw, is conspicuously less than in males and even large females of the *Rambi* and *Pappan*; though they are proportionally larger than in the *Kassar*. It is further remarkable that the frontal ridges of the skull, instead of uniting upon the vertex to form a single sagittal crest (as in the *Rambi*), or continuing separate and well apart throughout (as in the *Pappan*), approach to contact upon the vertex but without uniting; which is very likely to prove a constant and specific distinction.

tion, as the present old male shews much irregular deposition of bone externally to its contiguously double sagittal crest. The long bones of the limbs, though fully as stout as in the *Rambi* and *Pappan*, and about twice as stout as those of our old female *Kassar*, yet probably do not exceed the corresponding bones of the full grown male *Kassar* in length; being very much shorter than those of the adult *Rambi* and *Pappan*; and this remarkable brevity of limb, combined with the conspicuous differences in the skull and sundry other distinctions, can scarcely be considered otherwise than as indicative of specific peculiarity.

Of the five *Rambis* sent, there is unfortunately no specimen of a male of the largest size, comparable to that of which the skull is figured in the 1st and 2nd plates accompanying the former memoir: but there are two large full-grown females (including that ticketed *Mias Chapin*), and also a full grown female of smaller dimensions (which was labelled *M. Pappan*;) with a male of superior age and stature to the male *Pappan* presented formerly by Mr. Nicholls; and also a young male, with the last molars brought into wear, but which nevertheless had not nearly attained its full growth, which bade fair to rival that of the gigantic Sumatran male already noticed.

The specimen to which the name *Mias Chapin* was attached, appears (as already mentioned) to be a large old female *Rambi*, very remarkable for the enormous size and vertically elongated form of its orbital cavities, which measure 2 in. by nearly  $1\frac{3}{4}$  in. across. Its skull is larger, though less massive, than that of the female *Rambi* figured in the former memoir: the muzzle is conspicuously more slender, measuring but  $2\frac{5}{8}$  in. in greatest width (outside the canines), instead of  $2\frac{7}{8}$  in.: and whereas the coronoid process of the lower jaw in the former specimen is smaller and about on a level with the condyle, in the present example (labelled *Chapin*) the posterior or condyle process is unusually prolonged, and raises the skull (with lower jaw *in situ*) so remarkably, that placing it on a level surface together with the other skull noticed, the zygoma of the so-called *Chapin* not only overlaps that of the other, but its lower edge is about  $\frac{1}{16}$  in. higher than the upper edge of the zygoma of the other specimen: \* the nasal bones, which in the other are united and ascend to the very summit of the *glabella*, in this skull continue separate, and reach only to the lower portion of the *glabella*. This skeleton is very deficient, wanting the *sacrum* and most of the bones of the hands and feet: but all of the long bones are present, with the shoulder-blades and rest of the *pelvis*; the epiphyses being completely soldered. The limb-bones are even rather longer than in the great female *Pappan*, and in fact exceed in length those of any other of our full-grown speci-

mens: the *humerus* measuring 15 in., the *ulna* (to tip of styloid process)  $15\frac{3}{4}$  in.; femur  $11\frac{1}{2}$  in.; and tibia  $10\frac{1}{3}$  in.: circumference of middle of trunk of humerus  $3\frac{1}{8}$  in.; and of femur  $2\frac{7}{8}$  in. The few digital bones seem to accord in dimensions with the corresponding bones of our male *Pappan*. The extreme length of the *scapula* is  $8\frac{1}{4}$  in.; and of *pelvis*  $10\frac{7}{8}$  in.: clavicle 8 in. This specimen is marked as having been procured in Sadong (in Borneo).

\* In Prof. Owen's figure of a female *Rambi* skull (*Zool. Trans.* I, pl. 35), the condyle-process is similarly elongated.

The next specimen, which was erroneously marked *Pappan*, we consider to be a small female *Rambi*, though fully mature and even old, as shewn by the almost complete obliteration of the cranial sutures, the ankylosis of the various epiphyses, and the amount of attrition of all the teeth. The cranial ridges are very small; and the sagittal crest is hardly at all raised, but nevertheless exhibits a tendency to rise along the median line of the skull, between the frontal ridges which converge from the temples, and to be prolonged in front, anterior to the convergence of the latter, which takes place unusually far back: the nasal bones are united and singularly minute, actually not rising so high as the wide part of the orbital cavities; and the latter are small and circular, measuring barely  $1\frac{3}{8}$  in every way. The skull considerably resembles that of the female *Rambi* formerly figured, only that the sagittal crest is so much smaller; the *zygomata* being also more raised (in consequence of the greater prolongation of the condyle process of the lower jaw); and the orbits are smaller and more circular, and surmounted by much slighter ridges: consequently the face is flatter, and the sockets of the incisors are also less protruded. The skeleton is unfortunately very imperfect, wanting most of the bones of the hands and feet, and one *tibia* and *fibula*: a portion of the lower jaw, with the canine, first præmolar, and part of the second, is also lost: but the other long bones are present, and the *pelvis* is complete. Length of *humerus* but  $13\frac{1}{2}$  in.; of *ulna*  $13\frac{7}{8}$  in.; of *femur*  $10\frac{3}{8}$  in.; and of *tibia* 9 in.: circumference of middle of *humerus*  $2\frac{7}{8}$  in.; and of *femur*  $2\frac{3}{4}$  in.: metacarpal bone of middle finger  $3\frac{1}{8}$  in. metatarsal of corresponding toe  $3\frac{3}{4}$  in.: *os calcis* 2 in.: Total length of *scapula* (with *acromion*  $1\frac{1}{8}$  in.; and of *pelvis*  $9\frac{7}{8}$  in.; extreme breadth apart of the *ilia* (or hips)  $10\frac{7}{8}$  in.: clavicle  $6\frac{3}{8}$  in. This specimen also is marked from Sadong in Borneo.

The third female *Rambi* is of large size and fully mature, with the various epiphyses well soldered: but it has even less trace of sagittal crest than the last; the frontal ridges meeting as far back upon the skull, but not quite uniting, and a small mesial ridge rising between them above the vertex: the orbits are moderately

## ORANG-UTAN.

large and a little elongated vertically, measuring  $1\frac{5}{8}$  by  $1\frac{1}{2}$  in.; and the nasal bones are united and ascend a little into the glabella. Size about that of the first specimen (marked *Chapin*), but the muzzle rather broader or  $2\frac{1}{16}$  in. This specimen is nearly perfect: but the face is disfigured by a bullet which had knocked away the inner half of the right orbit and a tolerably large piece from the occiput; which fragments are lost. Length of *humerus*  $14\frac{3}{4}$  in.; *ulna*  $15\frac{1}{4}$  in.; *femur*  $11\frac{5}{8}$  in.; *tibia*  $10\frac{5}{8}$  in.: circumference of middle of trunk of *humerus* 3 in.; and of *femur*  $2\frac{3}{4}$  in.: metacarpal bone of second or middle finger  $4\frac{5}{16}$  in.; first phalanx of ditto  $3\frac{1}{16}$  in.; second phalanx  $1\frac{1}{16}$  in.: metacarpal bone of thumb  $2\frac{1}{8}$  in.; first phalanx of ditto  $1\frac{1}{8}$  in.: metatarsal bone of middle toe  $3\frac{1}{8}$  in.; first phalanx of ditto  $2\frac{1}{8}$  in.; second phalanx  $1\frac{3}{4}$  in.: metatarsal bone of hallux  $2\frac{1}{16}$  in.; first phalanx of ditto  $1\frac{3}{16}$  in.; and ungual (!)  $\frac{1}{16}$  in. Total length of *scapula*  $9\frac{1}{4}$  in.; *clavicle*  $7\frac{5}{8}$  in.; extreme length of *pelvis*  $11\frac{1}{4}$  in.; and extreme breadth of *pilia* 12 in.

The two remaining *Rambis* are males: and the first to be noticed is a young animal, whose skull had obviously not attained its full dimensions, though the last true molars had been brought into wear: but the general massiveness of this skull indicates that the animal would probably have become a male of the largest size: the sagittal crest had begun to rise on a grand scale; and the frontal ridges converge directly to it, although these are scarcely indicated for  $\frac{3}{4}$  in. before their junction. The teeth are more crowded than in the full grown animal; the inter-space between the upper canine and outer incisor, which in our large Sumatran male, is  $\frac{3}{8}$  in., being scarcely  $\frac{1}{4}$  in.; and the first false molar, instead of being completely posterior to the canine, advances considerably on its outer surface posteriorly; in the lower jaw, also, there is a bony inter-space between the canine and first false molar in the large mature male, but not in the adolescent male: nasals partially ankylosed, and continued upward to the lower part of the *glabella*: epiphyses of the *humeri* considerably ankylosed, and also, those of the *tibiae* and *fibulae* but not of the *radii* and *ulnae*. This skeleton also is tolerably complete. Length of *humerus*  $14\frac{5}{8}$  in., of *ulna*  $13\frac{3}{4}$  in.; of *femur* 10 in.; and of *tibia* 9 in.: circumference of middle of trunk of *humerus*  $2\frac{1}{16}$  in., and of *femur*  $2\frac{5}{16}$  in.: metacarpal bone of middle finger (the epiphyses beginning to ankylose)  $3\frac{3}{4}$  in.; first phalanx of ditto  $2\frac{7}{8}$  in.; second phalanx  $1\frac{7}{16}$  in.: metacarpal of thumb  $1\frac{7}{8}$  in.; metatarsal of middle toe  $3\frac{9}{16}$  in.: first phalanx of ditto  $2\frac{3}{4}$  in.; second  $1\frac{5}{8}$  in.: metatarsal of hallux  $1\frac{7}{8}$  in.; *Clavicle*  $6\frac{1}{8}$  in. Extreme length of *scapula* (minus epiphysis)  $7\frac{1}{2}$  in.: of *pelvis* (with ischial but not iliac epiphysis)  $9\frac{3}{4}$  in.; and extreme breadth at the hips  $10\frac{1}{4}$  in.

## ORANG-UTAN.

The next is a mature male, but certainly not of the largest dimensions: being about the size of the great females already described; and not otherwise recognisable from them than by the general massiveness of the skull (which is remarked at the first glance), and less conspicuously than usual in the present instance, by the form of the *pelvis*. The superciliary ridges are much broader than in any female skull; and the *zygomata* equally robust: the sagittal crest is also broad and well developed: nasals distinct, and reaching up to the lower part of the *glabella*. Skeleton tolerably complete; wanting most of the ungual phalanges and some other small bones. Length of *humerus*  $14\frac{3}{4}$  in.; of *ulna* (with loose epiphysis)  $15\frac{1}{8}$  in.; of *femur*  $11\frac{1}{8}$  in.; *tibia*  $9\frac{7}{8}$  in.: circumference of middle of trunk of *humerus*  $3\frac{1}{8}$  in.; and of *femur*  $2\frac{3}{4}$  in.: metacarpal bone of middle finger  $4\frac{1}{4}$  in.; first phalanx of ditto  $3\frac{1}{16}$  in.; second phalanx  $1\frac{1}{16}$  in.: metacarpal of thumb  $1\frac{3}{16}$  in.; first phalanx  $1\frac{1}{8}$  in.: metatarsal of middle toe  $4\frac{1}{8}$  in.; first phalanx of ditto  $2\frac{1}{8}$  in.; second phalanx  $1\frac{1}{16}$  in.: metatarsal of hallux  $2\frac{1}{16}$  in.; *clavicle*  $7\frac{1}{4}$  in.; *scapula*  $8\frac{3}{8}$  in.; *pelvis*  $10\frac{3}{4}$  in. in extreme length, and  $11\frac{3}{4}$  in. broad at the hips. This specimen was marked *Mias Rambis* by Sir J. Brooke; and is also from Sadong in Borneo: the three skeletons received from Sadong having unfortunately been prepared by interment in the ground; and the present being the most complete of them and otherwise the least injured.

We now come to the female *Pappan* already noticed; which, though of greater size than the male described on a former occasion, with considerably longer and broader *pelvis*, has nevertheless a smaller skull, less prominently developed jaws, and conspicuously smaller teeth: the *zygomatæ* arch is shorter and a little weaker than in the male; but the superciliary ridges and width of the bony orbits are much the same, and in fact there is little further difference between the two skulls: the bony crests on the vertex are less prominent in the female, and they approach to within  $\frac{3}{4}$  in. of each other; whereas in the male they remain 1 in. apart where most approximated: length of base of skull, from between the middle incisors to the anterior margin of the occipital foramen,  $6\frac{7}{8}$  in. in the male, and  $6\frac{1}{8}$  in. in the female: breadth of *zygomata* apart  $6\frac{5}{8}$  in. in both. This skeleton is also nearly perfect. Length of *humerus* 15 in.; of *ulna*  $15\frac{5}{8}$  in.; *femur*  $11\frac{1}{2}$  in.; *tibia*  $10\frac{5}{8}$  in.; circumference of middle of trunk of *humerus*  $3\frac{1}{4}$  in.; of *femur* 3 in.; metacarpal bone of middle finger  $4\frac{1}{8}$  in.; first phalanx  $3\frac{1}{8}$  in.; second  $1\frac{1}{16}$  in.; metacarpal bone of one thumb 2 in., of the other somewhat less and, bearing a very short first phalanx, only  $\frac{7}{8}$  in.; metatarsal bone of middle toe 4 in.; first phalanx 3 in.; second  $1\frac{3}{8}$  in.; metatarsal of hallux  $2\frac{1}{2}$  in.; *clavicle*  $7\frac{1}{4}$  in.; *scapula*

## ORANG-UTAN.

$8\frac{1}{2}$  in. in extreme length: and *pelvis*  $10\frac{1}{2}$  in. long, and  $11\frac{1}{4}$  in. broad at the hips.

Lastly, we arrive at the new species, which may be designated *PITHECUS CURTUS*. It is perhaps the genuine *Mias Chapin* of the Dyaks. The specimen is decidedly male, and well advanced in years; and the skull has a more anthropoid appearance than that of any other Orang known. This chiefly results from the much reduced prolongation of the muzzle, while the cheek-bones project remarkably, giving a sort of Kalmuk expression to the skull! The absolute projection of the maxilla, in a horizontal line carried from the lower margin of the orbital ring, is, in our large Sumatran male *Rambi* skull, fully 3 in.; in the male *Pappan* it is about the same; in the female *Pappan*  $2\frac{1}{2}$  in.; in the old female *Kassar* (a much smaller animal) about  $2\frac{1}{4}$  in.; and in the great male *CURTUS* barely 2 in.! Extreme breadth of *zygomath* 7 in.: height of the skull, with lower jaw *in situ*, 11 in.: length, in a straight line, from the summit of orbital cavity to between the incisors.  $4\frac{1}{4}$  in. (the same measurement being of the male *Rambi*  $5\frac{1}{8}$  in., and in the male *Pappan*  $4\frac{5}{8}$  in.): length from occipital foramen to base of upper incisors 6 in. (in the male *Rambi*  $7\frac{1}{8}$  in. and male *Pappan*  $6\frac{7}{8}$  in.): length of bony palate 3 in. (in the others  $3\frac{7}{8}$  in., and  $3\frac{5}{8}$  in.): orbital cavities  $1\frac{5}{8}$  by  $1\frac{1}{2}$  in. across: extreme width of bony orbits apart externally 5 in.: extreme breadth of ascending ramus of lower jaw  $3\frac{7}{8}$  in.; height of the condyle  $4\frac{3}{8}$  in.; length of grinding surface of the upper molars  $2\frac{1}{8}$  in. The skeleton is fortunately nearly perfect. Extreme length of *humerus*  $13\frac{1}{4}$  in.; *ulna*  $14\frac{3}{8}$  in.; *femur*  $10\frac{3}{8}$  in.; *tibia*  $9\frac{3}{8}$  in.; circumference of middle of trunk of *humerus*,  $3\frac{1}{4}$  in.; of *femur*  $2\frac{7}{8}$  in. (length and circumference of *humerus* of old female *Kassar*  $12\frac{3}{4}$  and  $2\frac{1}{4}$  in.; ditto of *femur*  $9\frac{7}{8}$  in. and  $2\frac{1}{4}$  in.): length of metacarpal bone of middle finger  $3\frac{7}{8}$  in.; first phalanx of ditto  $2\frac{1}{8}$  in.; second  $1\frac{1}{8}$  in.; metacarpal bone of thumb  $2\frac{1}{8}$  in.; first phalanx  $1\frac{1}{8}$  in.; metatarsal bone of middle toe  $3\frac{1}{8}$  in.; first phalanx  $2\frac{3}{4}$  in.; second  $1\frac{5}{8}$  in.; metatarsal bone of *hallux* 2 in.; clavicle  $6\frac{7}{8}$  in.: extreme length of *scapula*  $8\frac{3}{4}$  in.: of *pelvis*  $10\frac{1}{8}$  in.; and breadth at the hips 11 in. Length of the vertebral column, from atlas to *sacrum*, measured internally,  $16\frac{1}{4}$  in.; in the scarcely full grown male *Pappan*,  $17\frac{1}{2}$  in., and in the old female *Kassar*,  $15\frac{1}{4}$  in.: *axis*-vertebra soldered to the next. As compared with the *Rambi* and *Pappan*, the metacarpals and metatarsals are shorter, and the first phalanges of the fingers and toes are longer.\* A friend who has resided long in Borneo and has examined numerous skulls of Orang-utans (including those which have passed through the hands of Sir J. Brooke), informed Mr. Blyth, that he has remarked in the adult and aged specimens of the *Rambi* and *Pappan*, that, the canines are

## ORANG-UTAN.

always perfect; whereas in those of the small *Kassar* they are as regularly broken or worn down to about a level with the incisors. This remark is borne out by the series of skulls now under examination. The canines are long and unbroken in all the specimens of the *Rambi* and *Pappan*; and are ground down in the old female *Kassar*, and also in the old male *P. CURTUS*! Denoting probably a difference of food. Moreover, the same gentleman informs me that different species of these animals do not appear to inhabit the same district; and he thinks that the *P. OWENII* represents, in the southern part of the great island, the *P. MORIO* of the northern part.

With the grand series of skulls and skeletons of adult Orang-utans now subjected to examination, amounting to twelve in all (*viz.* 3 males and 4 females of *PITHECUS BROOKEI* or *Mias Rambi*, 1 male and 1 old female of *P. SATYRUS* or *M. Pappan*, one old male of the *P. CURTUS* or *M. Chapin*?, an old female of the *P. MORIO* or *M. Kassar*, and the adolescent female with short fore-arms, provisionally designated *P. OWENII*,—in addition to Prof. Owen's excellent lithographs of the male *Kassar* and of male and female *Rambi* in the *Trans. Zool. Soc.*, Vols. I and II), the observer is first struck with the very obvious and conspicuous distinctness of the comparatively puny *Mias Kassar*, and of the adolescent small skeleton, from all the rest. The next glance suffices to separate the *Rambi*, *Pappan*, and *P. CURTUS*: the last being quite as thoroughly distinguished apart by the *tout ensemble* of its appearance, as the *Pappan* is by its conspicuously double-crested vertex. No zoologist, accustomed to the discrimination of specific characters, would hesitate, with the present series of skulls before him, to acknowledge the distinctness of each of these three, but such an observer would ponder for a while over the remarkable female *Rambi* skull with enormous and vertically oblong orbits, and would doubtless hesitate in regarding it as specifically identical with the old female *Rambi* of small size; so great is the contrast between them. Presuming, however, that he arrived at the conclusion here ventured upon, it still follows that the *Rambi* is subject to an extraordinary amount of variation for a wild animal; and this, although it may not invalidate the opinion of its distinctness from the *Pappan* and *P. CURTUS*, nevertheless prompts a reconsideration of the grounds for the view formerly expressed, with regard to the specific distinctness of the small specimen having short fore-arms. From the detached state of the epiphyses of its limb-bones, it is certain that that specimen was not full-grown; and as those of the *ulna* at least (as shewn by the adult male *Rambi*, and also by that of the male *Pappan*), are the last become ankylosed, it should follow that the fore-arm continues to

# OVIS AMMON.

increase in length after the upper arm and the leg had ceased to grow : but the difference is still too great to be thus accounted for satisfactorily : and upon re-comparison of this specimen with the undoubtedly aged female *Kassar*, Mr. Blyth, deem it prudent to await the further evidence which Sir J. Brooke has kindly promised that he would endeavour to procure and send, before venturing to confirm or modify his previously expressed opinion on the subject.

This fact would appear certain, that the partial ankylosis of the epiphyses of the limb-bones does not rigorously denote cessation of growth, unless the female Orangs attain to greater stature than the males, which is most unlikely. It would seem rather, that as the earthy salts are continuously absorbed and re-deposited, some continuance of extension supervenes, until finally checked and stopped by the considerably increased deposition of bone. The skull also continues long to increase in size; after the last true molars have been brought into use.

As regards the sexual distinction, a practised eye discerns it readily in the adult skull, by its superior general massiveness in the male; and, in the skeleton, the larger and broader *pelvis* of course denotes the female animal, combined with a proportionally smaller and less robust skull than in the other sex. There is no reason to doubt the correct determination of sex in any one of the specimens here noticed.

The occasional but rare occurrence of the ungual phalanx to the *hallux* or great toe, would seem to be proper to no particular sex or species; for it exists in the male *Pappan* from Sumatra, and in the female *Rambi* from Borneo.

It now remains to connect the osteological with the external characters of the different species; to determine the stature attained by the largest males of the *Rambi*, *Pappan*, and also *Kassar*, to obtain further information of the *PITHECUS CURTUS*, and to verify or otherwise the *P. OWENII*. With the powerful aid of the accomplished Raja of Sarawak, we trust to be enabled ere long to resolve these various problems.

(2135) *OVIS AMMON?* Pallas. vel. "*O. Ammonoides*," Hodgson. The "*Nian*" or "*Nyna*" of the Bhoteahs.—(Pronounced nasally in one syllable.)

Measurement of a male of five years, according to the markings on the horns.

	Ft.	In.
From nose to base of horns. ....	1	1
Thence to insertion of tail. ....	5	1
Tail to end of hair. ....	0	3
Total, ...	6	5.

	Ft.	In.
Circumference of horn at base, ...	1	4 $\frac{3}{4}$
Length on the curve, tips broken. 2	10 $\frac{1}{2}$	

Winter pelage, above deep brown interspersed

# OVIS AMMON.

with grey, with a distinctly marked darker dorsal line, passing, (as in *O. montana*.) in a narrow stripe through the disc on the croup, even to the tip of the tail. Sides mixed hoary or slaty grey crown; disc on the croup well defined and dirty white, the hair appearing as if rubbed. The throat and neck beneath to the breast, white, sprinkled with scattered brown hair; the hair long, bushy and pendent; and from 6 to 7 inches in length, while that of the back is barely 2 inches, except on the dorsal line, where it is 3 inches, and on the ridge of the neck above 3 $\frac{1}{2}$  inches. Tail, above, brown, whitish at the sides, naked beneath. Under parts dirty white; medial line blackish, outside of the limbs with a dark list; lips, whitish; face paler brown than the body.

Front surface of horns, ..... 3 $\frac{1}{2}$  inches wide.

Inner lateral surface, ..... 6 inches wide.

Measurement of the bare skull of a male seven years old.

	Ft.	In.
Length of face to base of horns, ...	1	1
Length of horn on the curve, ..... 2	10	
Basal circumference, .....	1	4 $\frac{3}{4}$

These horns are weathered and much broken at the tips, and were probably about 3 ft. 3 inches long.

Description of a female, 6 years old by the marking of the horns.

	Ft.	Ins.
Nose to base of horns, .....	0	10 $\frac{1}{2}$
Thence to insertion of tail, ...	4	5
Tail, .....	0	3
Total, .....	5	6 $\frac{1}{4}$

	Ft.	Ins.
Length of horns on the curve, 1	4 $\frac{1}{2}$	
Basal circumference, .....	0	8

In the female, the colouring is lighter than that of the male, having more grey; and the throat and foreneck are slaty instead of white, and devoid of the long pendent frill which graces the other sex; the dark dorsal line, which in the male runs in a narrow stripe through the pale disc, ends in the female at the commencement of the disc, and the tail and croup are of the same canescent fawn colour; the disc is far more extensive than that of the male. Along the ridge of the neck above, from the base of the horns to about 10 inches beyond them, there is a mane of true woolly hair 6 $\frac{1}{2}$  inches long, gradually fading into the crisp quilly hair of the dorsal line. There is no dark list down the outside of the limbs, but the colour is pale fawn.

Front surface of horns, ..... 1 $\frac{3}{4}$  Ins. broad.

Inner lateral surface, ..... 3 „ inches.

In both sexes there is a beautifully soft inner coating of fine pushmeena wool of a pale mouse colour.

The height of the animals is not given, as the limbs are defective in the specimens.

The above measurements were taken with care,

## OVIS BURRHIEL.

and although the male appears somewhat superior in size to Mr. Hodgson's, the general correspondence is evident enough.

*Ovis Ammonoides*, Hodgson, was dedicated to Mr. Hodgson as *Ovis Hodgsonii*, some time before the publication of the name *ammonoides* in the 'Proceedings of the Zoological Society' for July 1840. On the same occasion, Mr. Blyth pointed out that Captain Hutton's *Ovis cycloceros* had been priorly named by him *Ovis Vignei*.

*Ovis Ammon*, Pallas; *Ovis montana*, Desmarest; *Ovis nivicola*, Eschscholtz. is distinct from *Ovis montana* of North America and Mr. Blyth refers to it, though with considerable hesitation, the horn in the Museum of the Royal College of Surgeons, London, (vide Taylor's plate, figs. 3 and 4,) for which was suggested the provisional name *sculptorum*.

(2136) OVIS POLII, Blyth. Founded on a magnificent frontlet and horns brought by Lieutenant Wood from the Pamir steppe; combined with the notice quoted from Marco Polo, which refers undeniably to the same animal. Of the distinctness of this superb species, there can be no doubt whatever; and the frontlet is figured in Taylor's plate, figs. 1 and 2.

(2137) OVIS CALIFORNIANA, Douglas. Description cited from 'Zoological Journal;' and the horns fully described by Mr Bligh, and figured in Taylor's plate, fig. 5. An unquestionable species.

(2138) OVIS NAHOOR, Hodgson. Described from specimens, amongst which was a hornless female; and first clearly established as distinct from *O ammon*. †\*

(2139) OVIS BURRHIEL, Blyth. Described from a fine male; and the horn of a still older one. It would seem, however, that Mr. Blyth was wrong in assigning to it a loftier altitude of haunt than that of *O. nahoor*. Capt. Smith has informed him that *O. burrrhel* and *O. nahoor* keep always in separate flocks, and are never seen on the same feeding ground; the Burrhel seldom ascending above 16,000 feet elevation, while the Nahoor goes much higher: Both bleat like domestic sheep. Near the Boorenda Pass, the Burrhel is much more plentiful than the Nahoor; but the latter is far more extensively diffused over the Himalaya generally. At the close of summer, when the snow is nearly melted away, a very nutritious grass grows abundantly under a thin coating of snow, and both species become

## OVIS VIGNEI.

exceedingly fat by feeding upon it, i. e. in the months of August, September, and October. At this time they can only be compared to the prize animals exhibited at the Smithfield shows, and they run with considerable difficulty, though still being far from easy of approach. In winter, when snowed in, they actually browse the hair off each other's bellies, many together having retired under the shelter of some overhanging rocks, from which they come out wretchedly poor. They produce one or two young, (commonly two,) in June and July. In Taylor's plate, the representations of the horns of these two species were unluckily transported; No. 6 referring to *O. burrrhel*, and No. 7 to *O. nahoor*.

*Ovis Burrhel* is deficient in the suborbital sinuses, and the same deficiency occurs in *Ovis Nahoor*.—*Beng. As. Soc. Jour.* No. CLXXVI. April, 1847.

(2140) OVIS CYLINDRICORNIS, Blyth. This is the least satisfactorily established of all the species in Mr. Bligh's monograph: it resting on a communication from Col. Hamilton Smith, relative to a species which must have been very different from either of those known to Mr. Blyth though described from memory only by Col. H. Smith (one of the most experienced of Zoologists in the history of the *Ruminantia*.)

(2141) OVIS GMELINI, Blyth. Described from very fine specimens of the male, female, and young; and identified with a species long ago rudely figured by the younger Gmelin, and the horn by Pallas; and Gmelin's description of the habits quoted, with further original information. Head figured in Taylor's plate, No. 9.

(2142) OVIS VIGNEI, Blyth. Described from a coloured figure taken from life, and from two pairs of horns, the distinctness of which from those of all the other species is most obvious: vide Taylor's plate, fig. 9. A skin of this animal was described by Pennant as the "Bearded sheep," but was confounded by him with *O. tragelaphus* (vide X, 877); and there is a brief notice and very passible figure of the species, taken from an animal killed in the vicinity of Persepolis, in Lieutenant Alexander's 'Travels from India to England,' &c. (1827.) It again appears as the "Wild sheep of the Hindu Koosh," described by Capt. Hay, J. A. S. IX, 440; and as *Ovis cycloceros*, Hutton, 'Calcutta Journal of Natural History' II, 514, and pl. XII, being again noticed by the latter gentleman in J. A. S. XV, 152. It may be observed that Capt. Hay remarks this species to differ from *O. tragelaphus* "in having a lachrymary sinus; and Capt. Hutton also described "a moderate-sized lachrymal sinus, which appears to secrete, or at all events contains, a thick gummy substance, of good consistency, and of a dull greyish colour. The Afghan and Belooch hunters," he adds, "more especially the latter, make

use of this gum, by spreading it over the pans of their matchlocks, to prevent the damp from injuring the priming." We may, therefore, rest satisfied of its existence in this species, which is nevertheless most closely allied to the next.

(2143) *OVIS MUSIMON*, L. Described by Mr. Blyth from life, and a further notice given in J. A. S. X, 878. "The Argalis and Moufflons (not to mention the *Tragelaphi*)," writes Mr. Hodgson, "seem to form two striking groups among the wild Sheep: Our Nahoor is a complete Moufflon; hence asks Mr. Bligh if the Corsican animal is, like the Himalayan, devoid of suborbital sinuses." In reply to this the Prince of Canino states that it is so devoid; but Mr. Hodgson is mistaken in approximating the Nahoor and Burrhel to the Moufflon of Corsica. These two Himalayan species, instead of being "complete Moufflons," are (so far at least as their horns are concerned) unlike *O. musimon* and form a little group *per se*, unless *Ovis cylindricornis* should prove to range with them; and the Moufflon is quite excluded from his definition of "round-horned" sheep, for which group Mr. Blyth presumes the appellation *Pseudois* is proposed. Their being "furnished with a well developed tail," will not exclude the Californian Argali, the tail of which is described as "eighteen inches long!" Mr. Ogilby long ago remarked the absence of suborbital sinuses in *Ovis nahoor*; and the group formed by *Ovis nahoor* and *Ovis burrhel* was distinct-

ly indicated in Mr. Bligh's monograph (vide J. A. S., X, 867), being estimated there, as he still thinks, at its true value.

Should it prove that *O. musimon* is really devoid of the facial cavities, the value of this character would fall to a mere specific distinction; for however the wild sheep may be arranged into minor groups, the *O. Vignei* (which has the sinuses) could scarcely be placed in a different subdivision from *O. musimon*. And to the same group must be referred *O. Gmelini* and *O. ophion*, though altogether perhaps forming a subsection of it. Both in *O. Gmelini* and *O. Vignei*, we find indications of affinity with the African *O. tragelaphus*.

(2144) *OVIS OPHION*, Bligh. Founded on the coloured figure and description, by M. M. Brandt and Katzeburgh, of a specimen in the Berlin Museum.

(2145) *OVIS ARIES*, L. The domestic sheep. Several wild types, as is still strongly suspected: but none of those above enumerated; unless, to a partial extent, *O. Vignei*, though even this very doubtful.

(2146) *OVIS IXALUS PROBATON*, Ogilby. Described from a hornless specimen, which is at least closely allied to

(2147) *OVIS TRAGELAPHUS*, Pallas. A well known species. Described from specimens, observed both alive and in museums.—*Ben. As. Soc. Journ. April 1847.*

## P.

(2148) *PADRI*, the Tamil and Malayala name of a tree *Bignonia chelonoides*, which is about twenty feet long and eight inches in diameter; it produces a small white flower in shape like the fusca, or rather the snow-drop, which has a most powerful fragrance, they are prescribed in infusion as a cooling drink in fevers. The leaves, if steeped in a portion of lime-juice, make a most grateful and cooling drink. This is one of the sacred trees, and considered the property of the pagoda; and the flowers are held sacred for the purpose of decorating the dancing-girls' heads on days of ceremony.—*Edye M. S. C.*

(2149) *PALMYRA* OR *TADMOR* (pronounced by the Arabs Toodmor), both signifying the place of Palm trees, is first mentioned as having been built by Solomon. From that time till after the captivity of the Roman Emperor Valerian by the Persians but little is known of it. It rose to the highest opulence and splendour under Odenatus, whose dominions extended from the Euphrates to the Mediterranean. But its chief interest is connected with the wife of Odenatus, Zenobia Queen of the East.

The increasing power attracted the notice and jealousy of Aurelian who having defeated her in two pitched battles, laid siege to Palmyra. Soon after the surrender of the city, the Palmyrenes revolted against the Emperor, who in consequence entirely destroyed the city, and put the greater part of the inhabitants to death. He afterwards restored the temple of the Sun, and gave permission to the remnants of the Palmyrenes to rebuild and inhabit their city. The pile of building on the left is the temple of the sun, consisting of an immense court, of which the ruins are spread over a space of 220 yards. It is surrounded by a stately wall, adorned with pilasters within and without. Two rows of marble columns, of which about sixty remain entire, formed a colonnade within the court, which is now occupied by the Arab huts. The great colonnade which forms the principal feature in the drawing, extends more than half a mile in length, and probably was the main street in the city, from which others branched out laterally; it was entered by an archway, and terminated by a large building, of which the portico

# PALÆORNIS VIRIDIMYSTAS.

alone remains. Innumerable columns and ruins of temples, are scattered over the plain. Its peculiar interest is not confined merely to architectural details, but to its position in the desert, and its utter loneliness. I may quote the sentiments of Lord Lindsay who writes thus :—

“An awful stillness,—a lifelessness pervades the ruins,—they stand as lonely and silent as when the last of the Palmyrenes departed and left the city of Zenobia to silence and decay.”

(2150) PALA MARAM, the Malayala name of one of the jungle fruit trees. It produces a fruit which the natives use medicinally, but as timber it is of no value.—*Edye, Mal. & Can.*

(2151) PALAWAN. The south western-most island of the Philippine group, is a long narrow strip of land extending nearly south west and north east 250 miles, forming the eastern boundary of the China Sea, from latitude 8°. 13' to 11° 17' N. The northern extremity is a narrow peninsula about 60 miles in length, consisting of a mass of limestone rock, rising precipitously from the sea to 200 to 300 feet in height, which the native inhabitants climb readily in search of edible birds nests, their chief occupation. It is along the eastern coast of the island that ships proceed when ships are bound up the China Sea late in the seasons, when the north east monsoon is expected, and derives from this the name of the Palawan passage.—*Journ. Ind. Arch.*

(2152) PALLAGA PAYANYE, the Malayala name of a tree, which means “plank-wood.” It grows to about twelve inches in diameter, and fourteen feet in height. It is soft and light, and is used by the natives for county vessels and catamarans. This wood, with all the light jungle-woods, are of little value, in consequence of their early and rapid decay.—*Edye. M. and C.*

(2153) PALMA BRAVA, Nibong, Tagala of Mindoro, used by the wild tribes of Mindoro to form their bows and point their arrows.

(3154) PALÆORNIS VIRIDIMYSTAS, Blyth. Size about that of *P. malaccensis*; closed wing 6 in. Colour bright golden green, the green deeper than usual in this genus with light indigo-blue on the primaries and tail, axillaries, and fore-part of the wing underneath bright yellow a broad band of peach-blossom red below the eye from bill to middle and lower portion of ear-coverts, rest of the latter green tinged with verditer monstachial streak as in *P. malaccensis* and others, but of a darkish green hue contrasting with the more yellowish green of the body: a slight pale duskyish streak also from nostril to eye and small red spot above the eye (conspicuous in the living bird). Bill duskish in the individual but with the upper mandible doubtless coral-red in the adult Irides dark greenish-hazel, surrounded by a white ring. Feet pale greenish-gray. Habitat unknown.—*Journal of the Asiatic Society of Bengal, p. 445.*

# PAPUANS.

## (2155) PANDANUS ODORATISSIMUS.

Sweet scented pandanus,	Keder, ARABIAN.

The terminal buds, and a portion of the leaves, their white base, are edible.

## (2156) PANDION HALLÆTUS, the osprey.

Soon as the sun, great ruler of the year,  
Bends to our northern climes his bright career,  
And from the caves of ocean calls from sleep,  
The finny shoals and myriads of the deep;  
When freezing tempests back to Greenland ride,  
And day and night the equal hours divide;  
True to the season, o'er our sea-beat shore,  
The sailing osprey high is seen to soar,  
With broad unmoving wing; and circling slow,  
Marks each loose straggler in the deep below;  
Sweeps down like lightning! plunges with a roar!  
And bears his struggling victim to the shore.  
The long housed fisherman beholds with joy,  
The well-known signals of his rough employ,  
And as he bears his net and oars along,  
Thus hails the welcome season with a song.

## THE FISHERMAN'S HYMN.

The osprey sails above the sound,  
The geese are gone, the gulls are flying;  
The herring shoals swarm thick around,  
The nets are launched, the boats are plying;  
Yo ho, my hearts! let's seek the deep,  
Raise high the song, and cheerily wish her,  
Still as the bending net we sweep,  
“God bless the fish-hawk and the fisher!”  
She brings us fish,—she brings us spring,  
Good times, fair weather, warmth, and plenty,  
Fine stores of chad, trout, herring, ling,  
Sheepshead, and drum, and old wives' dainty,  
Yo ho, my hearts! &c.

She rears her young on yonder tree,  
She leaves her faithful mate to mind 'em;  
Like us, for fish, she sails to sea,  
• And plunging shows us where to find 'em,  
Yo ho, my hearts! &c.—*Wilson, p. 83.*

(2157) PANGLIMA GAJAH, MALAY. The first word means a governor, or superintendent, and the other elephants. The office of superintendent of elephants at a Malayan court was one of considerable dignity.—*Journ. Ind. Arch.*

(2158) PAPUANS, or oriental negroes exist in the interior of New Guinea, where they are called by Mr. Muller *Mairassies*, and by Lieutenant Modera *Alfoeren* or *Alfoers*. The Papuan race extends from New Guinea eastward through

the Louisiade and Solomon Archipelagos to the New Hebrides where it co-exists with some tribes of Malaya-Polynesians, and still further to the Fiji islands which however are the extreme limit of the race in an Eastern direction. The Fijians are the aristocracy of their race. In a South direction the Papuans have evidently spread far and wide over the continent of Australia and occur even in Van Diemen's land, though their characteristics are greatly modified.

Writing on the leading characteristics of the Papuan Australian, and Malaya Polynesian nations Mr. G. Windsor Earl, M. R. A. S. says that the existence of a Negro race in the Indian Archipelago, so remote from the continent which is considered as the original seat of the race, has given rise to endless speculations as to how they get there, and probably will continue so to do until the end of time, for being a nation without a written language, and surrounded by others whose records are carried back to no very distant date, and whose traditions have become, from lapse of time, mere fables, this point can only rest upon circumstantial evidence, and therefore will ever prove liable to dispute. Their position in many of the larger islands as occupants solely of the mountain fastnesses, surrounded by people who evidently belong to a distinct race, has certainly put an end to those theories of the last century which attributed their origin to the shipwrecked crews of Arabian slave-vessels, and has led to a very general opinion that they were, in fact, the aboriginal inhabitants of the countries in which they are found. That their existence was not altogether unknown to the ancients is proved by the maps and writings of Ptolemy, the Alexandrian, who flourished soon after the commencement of the Christian era, and was the first to reduce geography to a system. In the last map of his volume, that which contains the "Aurea Chersonesus" and the "Iabades Insulæ," (supposed to have meant respectively the Malayan Peninsula or Sumatra and the Java Islands) he places a country far to the eastward of the Aurea Chersonesia, under the equinoctial line, which he states to be occupied by "Æthiopes Ichthyophagi," or "Negro fish-eaters;" the first term being that employed by the Romans to distinguish the black and woolly haired Africans from the Mauritanians and other brown races of the east; and the second, that usually applied to all nations who derived a portion of their subsistence from the sea.

The system of naming nations from the food which formed their chief means of support, seems to have been very prevalent among the ancients; witness "Hippophagi" the horse eating Tartars, "Lotophagi," Lotuseaters, &c. This system, although not to be recommended at the present day, has proved highly useful, for these names are sometimes found to contain the only existing

description of the habits of the people on whom they were conferred, as in the present instance. Dr Leichhardt in his late overland journey from Sydney to port Essington, found some tribes of genuine Lotophagi on the lagoons of the table land, as will come to be noticed below.

The position of this country with regard to the Aurea Chersonesus agrees well with that of New Guinea, the great seat of the Papuan race. The existence of a negro people, at so remote a spot, which he must have learned from the information of Indian navigators, seems, indeed, to have led Ptolemy into the great error of his system, for believing that the country of the "Æthiopes Ichthyophagi" formed part of the continent of Asia, he has made that continent, in his general map of the world, come round by the south and join the African continent about Point Prassum, in latitude 15° S. (the then southern known limit of the east coast of Africa), thus making the Indian Ocean and the seas of the Eastern Archipelago, form one vast Inland sea.

The most striking peculiarity of the Oriental negroes consists in their frizzled or woolly hair. This, however, does not spread over the surface of the head as is usual with the negroes of western Africa, but grows in small tufts, the hairs which form each tuft keeping separate from the rest, and twisting round each other, until, if allowed to grow, they form a spiral ringlet. Many of the tribes, especially those who occupy the interior parts of islands whose coasts are occupied by more civilized races from whom cutting instruments can be obtained, keep the hair closely cropped. The tufts then assume the form of little knobs, about the size of a large pea, giving the head a very singular appearance, which has, not inaptly, been compared with that of an old worn-out shoebrush. Others again, more especially the natives of the south east of New Guinea, and the islands of Torres straits, troubled with such an obstinate description of hair, yet admiring the ringlets as a head dress, cut them off and twist them into skull caps made of matting, thus forming very compact wigs. But it is among the natives of the north east of New Guinea, and of some of the adjacent islands of the Pacific, that the hair receives the greatest attention. These open out the ringlets by means of a bamboo comb, shaped like an eelspear, with numerous prongs spreading out laterally, which operation produces an enormous bushy head of hair which has procured them the name of "Mop-headed Papuans." Among the natives of the Feejee islands, (the easternmost limit of the Oriental negro race) the operation of dressing the hair, occupies the greater part of a day.

The hair of the beards and whiskers, which generally grows very thick and bushy, is arranged in little tufts similar to those of the head, and the same peculiarity is found to exist in the hair with which the breasts and shoulders of the

## PAPUANS.

men are often covered, but the tufts are here farther apart than on the head and chin.

This woolly or twisted hair is peculiar to the full blooded Papuans. A comparatively slight mixture with the brown-complexioned or Malayu Polynesian race appears to destroy the peculiarity. The hair of people of mixed race covers the surface of the head, or at least has done so in all cases that have come under my observation, and is sometimes only slightly curled. It is therefore very easy to distinguish the pure Papuans, and throughout this essay those only will be called by that name who possess this their leading characteristic.

The term Papuan is derived from a Malayan word "Papua or Prana Pua," crisp haired. The term "Tanna Papua" or "Land of the crisp-haired" is applied by them not only to New Guinea, but to all the adjacent islands which are occupied exclusively by this race. It is peculiarly applicable, and comprehensive, and so entitled to respect as having been conferred by a people who must have known them for ages before we even heard of their existence, that I trust the ethnologists of Europe will excuse me for retaining it in preference to the newly invented term "Melanesian" or "inhabitants of the black islands," which, although applicable enough to the Papuans, is equally applicable to the greater portion of the Australian tribes. The celebrated philologist, Marsden, has adopted the term "Negrito" or "little Negro" from the Spaniards of the Philippines, and has applied it to the entire race.

The features of the Papuans have a decidedly negro character; broad, flat, noses; thick lips; receding foreheads and chins; and that turbid colour of what should be the white of the eye which gives to the countenance a peculiar sinister expression. Their complexion is universally a deep chocolate colour, sometimes closely approaching to black, but certainly a few shades lighter than the deep black that is often met with among the negro tribes of Africa.

With regard to stature, a great difference is found to exist between various tribes, even in New Guinea, and which has led to much confusion in the descriptions given by travellers, who have, perhaps, each only seen a single tribe. On the south-west coast of New Guinea, within a space of one hundred miles, are to be found tribes whose stature is almost gigantic, and others whose proportions are so diminutive as almost to entitle them to the appellation of pigmies, while the manners and customs of each so exactly correspond as to preclude the supposition that these peculiarities can be other than accidental. It is difficult to account for these peculiarities, but as the stout and stalwart Papuans are met with only among those coast tribes who have maintained their independence, and at the same time have acquired many of the

## PAPUANS.

agricultural and mechanical arts from their neighbours the Malayu Polynesians while the pigmies are found only in spots where they have been driven to the mountain fastnesses, or have fallen under the influence of other races, we may conclude that their mode of life has much to do with this difference in point of stature and proportions.

With regard to form, the various tribes of Papuans differ as much as in stature. The more diminutive tribes, whose members chiefly come under the notice of Europeans from their existing in great numbers as slaves throughout the Moluccas are unprepossessing enough in appearance when in their natural state, but when under good masters, the regularity and wholesome nature of their diet, coupled with their apparent utter forgetfulness of their native land, produce a roundness in their neat clean limbs, and a sprightliness of action which is rarely met with among their more civilized neighbours the Malayu Polynesians. On the other hand the large Papuans are more remarkable for their strength than their symmetry. They have broad shoulders and deep chests, but a deficiency is generally found about the lower extremities, the splay feet and curved shins of the western Africans being equally, or even more common among, whom I may be allowed to term, the gigantic Papuans.

With regard to the general disposition of the Papuans, a great difference is found between those living in a state of independence, and those who exist in bondage among the neighbouring nations. The former are invariably found to be treacherous and revengeful, and even those who have long been accustomed to intercourse with strangers, the tribes of the North West coast of New Guinea, for example, are never to be depended upon, and the greatest precautions are always taken by those who visit them for purposes of trade. The wilder tribes generally avoid intercourse with strangers, if the force which lands is sufficiently great to cause alarm, but if otherwise they pretend friendship until an opportunity occurs, when they make a sudden and ferocious attack. But what distinguishes them most from their neighbours the Malayu-Polynesians, and even from the Australians, is the unextinguishable hatred they bear towards those who attempt to settle in their territory, and which is continued as long as a man of the tribe exists. It is, probably, this perfectly untameable nature that has led to their utter extermination in all those islands of the Indian Archipelago that did not possess mountain fastnesses to which they could retire to lead a life similar to that of the Boschmen of South Africa. We have had recent instances of this in Van Dieman's Land, Melville Island (N. W. coast of Australia) and at Fort Du Bus on the west coast of New Guinea, in all which settlements the

country was occupied by a pure or nearly pure Papuan race. In the former, hostility was continued as long a native remained on the island, and in the two last until the settlements were abandoned in despair. On the other hand, their neighbours, the Australians, have invariably submitted after a single trial of strength, while the Malayu-Polynesians, when not under the influence of other foreigners, have always evinced a desire to have strangers, especially Europeans, settled among them, as shewn by the people of the Moluccas when first visited by the Portuguese, and as displayed at the present time in those remote parts of the Indian Archipelago where the race maintains its ancient purity.

The untameable ferocity of the Papuans only exists as long as they remain in their native country. On leaving it their character seems totally changed, as far as regards this particular. The Papuan slaves who exist in great numbers in the eastern parts of the Archipelago are remarkable for their cheerful disposition and industrious habits, and nothing could exceed the orderly conduct of the remnant of the Van Dieman's Land natives after they had been hunted down, and removed to an island in Bass' Strait.

Before proceeding to describe the localities in which the Papuan race is now found, I think it proper to allude to certain of their customs which distinguish them from the Malayu-Polynesians, and which certainly are of Papuan, or at least of Negro, origin. One of these is the custom of raising the skin in cicatrices over various parts of the body, especially on the shoulders, breast, buttocks, and thighs. This must not be confounded with the tatooing or puncturing the skin which is practised by many of the Malayu Polynesian tribes, and which is never met with among the Papuans, as the scarifications which I am about to describe are unknown to the others. The skin is cut through with some sharp instrument in longitudinal stripes, and, if on the shoulder or breast, white clay, or some other substance, is rubbed into the wound, which causes the flesh below to rise, and these scarifications, when allowed to heal, assume the form of raised cicatrices, often as large as the finger. The process by which these cicatrices are produced and which I have had opportunities of watching in their progress from day to day until duly formed, is perfectly inexplicable to an European, who would be thrown into a fever by any one of the wounds which these strange people bear, two or three at a time, without complaining, but certainly not without suffering. It is, however, quite evident that the Papuans, and also the Australians, as will be mentioned below, possess a callousness of skin, or insensibility of pain, which is quite unknown among more civilized races.

Boring the septum of the nose is universally practised among the Papuans. In the first instance they wear a roll of plantain leaf in the

orifice which by its elasticity enlarges it to a sufficient size to admit the thigh bone of a large bird, or some other ornament, which is then worn extending across the face on all great occasions. Our sailors have a very quaint name for this practice, which often comes under their observation among the Papuan islands of the Pacific; they call it "sprit-sail yarding," after a cruel method they have of treating sharks and dog fish, which are frequently let go after having been hooked, a piece of wood being previously thrust through their nostrils, which projecting on either side, prevents them from getting their heads under water, and they die a lingering and painful death. I have never met with, or heard of, this practice of boring the nose among people of the Malayu-Polynesian race, and I may say the same with regard to the scarifications mentioned above. The latter, or rather those among them who are sufficiently barbarous to resort to personal disfigurement, seem to have adopted tatooing and boring the ears in lieu of the more coarse and painful ornamental work of the Papuans.

Filing or grinding down the front teeth until they become pointed is practiced by some of the tribes of New Guinea and of the adjacent islands of the Pacific. This custom however, is not confined exclusively to the Papuans, as it is practised also at the Pagi islands, on the west coast of Sumatra, the natives of which appear to be Malayu-Polynesians. This custom must not be confounded with one which is common among many of the Malayan and Bugis tribes, that of grinding down the front teeth until they become almost level with the gum.

Another singular custom which is only met with among the Papuans, or the tribes closely bordering on them, is that of dyeing the hair (which is naturally black) a reddish or flaxen colour, by using applications of burnt coral and sea-water in some instances, and preparations of wood ashes in others. This process seems to expel all the dark colour from the hair, leaving it of a flaxen tinge which appears to bear a close resemblance to the celebrated "*capillus flavus*" so much admired among the Roman ladies and which seems to have been produced by a similar process. The only Malayu-Polynesians that I have known to practice this custom are some of the natives of Timor Laut, Sermatten, and Baba, islands lying to the westward of New Guinea and not very remote. I am therefore induced to consider it as a Papuan, or rather, perhaps, as a "Negro" custom, for it is equally prevalent in many parts of Africa, especially among the Somalis, and other tribes in their neighbourhood. Travellers who have had opportunities of visiting our post at Aden in the course of their voyages between Europe and India by the overland route, may have observed this custom among the African coolies employed in coaling the steamer, who

sometimes appear with the plaster of coral still attached to their heads.

The Papuans, for the most part, exist only in a savage state, deriving a scanty substance from the productions of nature, living in conical shaped huts; or where they appear as occupants of the sea coast, roaming about in small canoes in search of food. Some of the more independent tribes, by which I mean those who have exclusive possession of the country they inhabit, have, however, adopted many improvements. In several parts of the north and of the south coasts of New Guinea, the villages consist of one large house, erected on piles, and occupied by all the married people, with a smaller one adjacent for the bachelors. These houses bear a very close resemblance to those of the Dyaks of Borneo, but are smaller and of more rough construction. Here the Papuans also cultivate fruits, yams, and sweet potatoes and keep hogs and poultry to kill for food, in fact are almost on a level, as far as regards agriculture, with the more uncivilized tribes of the Malayu-Polynesians, from whom, indeed, if we may judge from the names employed to designate their agricultural productions, they have derived this slight, but important advance they have made in civilization.

The weapons of the Papuans are heavy wooden clubs, spears or lances of nibong or other hard wood, and darts formed of a small kind of Bambu, provided with points of hard wood or of sharpened bone. The lances are projected generally by means of a becket of sennit about a foot and a half long, one end of which is provided with a toggle. This is held between the fingers, while the other end is fastened to the lance with what sailors call a "half-hitch" knot, which flies off when the lance is projected, thus allowing it to go free. The becket gives a greatly increased purchase to the thrower, but is much inferior in this respect to the womera or "throwing stick" of the Australians which will be described when we come to speak of that people. The darts are projected by means of a powerful bow, often six feet in length, with a bow-string of rattan. I suspect that this instrument was not originally Papuan, but has been adopted from the Polynesians. Stone axes, and knives of quartz are now superseded among all those tribes who have either direct or indirect communication with the traders of the Archipelago, by Parangs, or Chopping-knives of iron. Their agricultural instruments are mere stakes of wood, sharpened at one end, which proves sufficient to effect the rude interference with nature required by their mode of cultivation.

The art of navigation appears never to have been in a very advanced state among the Papuans, since their navigation has only extended to those countries which could be reached from the continent of Asia without entailing the necessity of going out of sight of land, nor are they

yet sufficiently advanced in the science of navigation to venture on any other than coasting voyages. Towards the eastern limits of the Papuan race, where they come in close contact, and are often mixed with the Polynesians, navigation is in a more advanced state than elsewhere, but this is evidently the result of contact with strangers, by whom, indeed the navigation is personally conducted.

The highest state of the art among the Papuans, without foreign assistance, is met with in Torres strait and upon the south coast of New Guinea. Here they possess large canoes of such construction and propelled in so peculiar a manner, that we must consider them purely Papuan. Some very excellent sketches of these canoes are given in Flinder's voyage, with so full a description that it will be unnecessary for me, to enter into minute particulars. These canoes or boats are from thirty to forty feet long, and the planks with which they are constructed are sewed together with the fibres of the cocoanut. Each is provided with an outrigger, and a platform of bamboo occupies the centre of the boat on a level with the gunwale. They are propelled in calm weather by paddles with long handles, the rowers all standing, as is generally the case among the Papuans. But the most striking peculiarity of these vessels consists in the sail, which is an oblong piece of matting set up in the fore parts of vessel by means of two poles or masts, to which the upper corners of the sail are fastened. These masts are moveable, and the sail is trimmed by shifting the head of one of the masts aft. According to my experience these boats sail very indifferently, except before the wind, but Captain Flinders, who had good opportunities of judging, maintains a more favourable opinion. They are often to be met with about the month of March three or four hundred miles down the North-East coast of Australia, the islanders being in the habit of making an annual voyage in this direction. The stopping places are usually the islands lying off the coast, where they obtained tortoise-shell and trepang, the chief objects of their voyages.

The natives of the south coast of New Guinea have very large canoes of a similar but more unwieldy construction, and propelled by a similar description of sail. These have never been seen far from the coast, and in fact are almost unmanageable from the difficulty experienced in steering such unwieldy masses with paddles alone. It is therefore difficult to conceive for what purpose they have been constructed, unless it should be for war, in which case their large size would give them an imposing appearance.

The New Guinea canoes generally are of light construction and are provided with an outrigger. The larger ones have an attap roof and are capable of containing an entire family, with household furniture and domestic animals.—*Journal*

## PAPUANS.

of the *Indian Archipelago*, 1849, page 682 to 689.

In a northwest direction from New Guinea, the Papuan race extends through the Moluccas, the Philippines and possibly to Borneo but in these islands they only appear in small and scattered tribes occupants of the mountain fastnesses.

The small islands which extend from New Guinea to Timor, with the exception of the Arru islands, are occupied by Malayu-Polynesians of the most decided character, but at Timor, especially near the north-east end, a race evidently of Papuan origin again appears, but never, as far as I have been able to ascertain after strict enquiry, in an absolutely pure state. These tribes are much oppressed by the Malayu-Polynesians who occupy the table land of the interior, and the slaves which are brought down to the settlements on the coast, and were formerly exported to Macao and other places, were chiefly of this race, which has led to very erroneous impressions with regard to the nature of the inhabitants of Timor on the part of those who have only met them at Macao, where the Negro character naturally prevails among them. Some tribes on the great island of Flores or Mangarai assume a more decided Papuan character, and there is said to be also a tribe of these people in the neighbourhood of the Timboro mountain on Sumbawa; but beyond this they disappear, and are not encountered again until we meet them on the Malayan Peninsula under the name of Semangs, occupying some mountain tracts in the states of Kidah, Perak, and Kalantan. The Andaman islands in the Bay of Bengal are occupied by a people of most decided Papuan character, who bear indeed, a very striking resemblance to the natives of Van Diemen's Land (Note C.) Hence they can be traced no further, unless the analogy recently discovered by Mr. Norris, the Assistant Secretary of the Royal Asiatic Society, between the Tamul language of the Coromandel coast and some of the Australian dialects may lead to the establishment of an affinity between the nations that use them. But this is a subject more peculiarly the province of Indian ethnologists, and they may probably find their labors lightened by having the leading characteristics of the Papuans and Australians more clearly defined.

Although the Andaman Islands lie in the direct track of ships navigating the eastern side of the Bay of Bengal, and were once actually occupied by a British establishment, the natives are scarcely better known now than they were during the earlier period of our intercourse with India. This is to be attributed to that feeling of hostility and aversion towards strangers which they possess in common with all the wilder Papuan tribes. Having learned by experience that they are utterly unfit to contend with the strangers who occasion-

## PARUS XANTHOGENYS.

ally visit or are thrown upon their shores, they usually, or, I may say, invariably, avoid all intercourse, and even the members of our establishments there only came into close contact with those individuals who had been taken captive in hostile encounters, or had been found in the woods or on the strand in a state of exhaustion from famine. A very full account of such particulars as could be acquired concerning them, will be found in one of the earlier volumes of the "*Asiatic Researches*," and also in Colonel Symes' Embassy to Ava. Their limbs are spare and ill proportioned, their bellies protuberant, the complexion black and the hair wooly. They have also a taste, so characteristic of the wilder Papuans, for daubing their heads with red ochre. They have canoes, but use small rafts when they wish to visit the islets. Both sexes go entirely naked, for the pieces of fringe that they wear about are rather intended for ornament than as a covering. They obtain fish by descending to the shore at low water and spearing those that are left among the reefs by the receding tide; or by catching them with small hand-nets, and depositing them in long wicker baskets which they carry slung from their shoulders. All these are characteristics of the wilder coast Papuans, especially those of Van Diemen's Land to whom indeed the Andamans bear a resemblance so striking as to excite surprise that two tribes who must have been separated during many ages, and who reside in climates so different, should be distinguished by precisely the same characteristics. The only point of difference that can be detected, consists in the knowledge on the part of the Andamans of the use of the bow and arrow, which was either never known to the Van Diemen's Land natives or has been neglected in favour of the dart or throwing spear, which is far better adapted to the open nature of their country. Many improbable stories, among others the usual one of wrecked slave vessels, have been invented to account for the singularity of a negro race existing on an island near the eastern shores of the Bay of Bengal, but at that time, it was not so generally known as it is at present how far and wide this race had spread over the remote East.—*Jour. Ind. Arch. January 1850, page 9.*

(2159) PARATY MARAM. Cotton tree; *Elæodendron*, the Tamil name of a tree. It grows to about twelve inches in diameter, and twelve feet long, and produces a nut which the natives eat, and on which wild animals feed. It is of not much value.—*Edye. M. & C.*

(2160) PARUS XANTHOGENYS of Dr. Jerdon's catalogue, for which Mr. Blyth proposes the name of *P. Jerdoni*. N. s. It much resembles *P. Xanthogenys*, Vigors, of the N. W. Himalaya; but is conspicuous by having the back less tinged with yellow, larger, portions of the plumage not so intense in hue, and the yellow sincipital streak is not continued forward

over the eye, as in *P. Xanthogenys* (verus). Length of wing 3 in; and of tail  $2\frac{3}{8}$  in; in *P. Xanthogenys* the wing varies from  $2\frac{1}{2}$  to  $2\frac{3}{4}$  in, and the tail measures  $2\frac{1}{8}$  in. This is the third species which has now been discriminated apart from *P. Xanthogenys*, Vigors; the others being *P. Spilonotus*, Blyth, from Nipal, Sikim, the Khasyas, &c., and *P. subviridis*, Tickell, Blyth, from the mountains.

He has further distinguished *P. Rubidiventris* of Nipal and Sikim from *P. Melanolophus*, Vigors, of the Simla and Masuri mountains; with which the *P. Melanolophus* of Jerdon's catalogue still requires to be critically compared.—*Beng. As. Soc. Vol. V*, 1856.

(2161) PATTI VAYNGU (which means dog-wood) the Malayala name of one of the inferior sorts of jungle-wood: it is considered of little use or value.—*Edye. M. & C.*

(2162) PAWANGS. The Rev. P. Favre, Apostolic Missionary of Malacca, mentions that the Pawangs are a class of men endowed with the power of performing the functions of priests, teachers, physicians, and sorcerers. Under any of these titles they have not much to do amongst the members of their own nation; many of them do not believe that the Pawangs have any supernatural powers as sorcerers or as priests, nor do they attribute any efficacy to the acts they perform under these two titles. The functions of priests amongst them consist only in performing some superstitious practices; since, as I have mentioned in another place, they have no true and real worship. But it is amongst the Malays that their skill is much in honor, and their persons objects both of veneration and of fear. The Malays are ridiculously superstitious on that point; they have a firm faith in the efficacy of the supplications of the Pawangs, and an extraordinary dread of their supposed supernatural power. The Malays imagine that they are endowed with the power of curing every kind of sickness, and of killing an enemy however distant he may be, by the force of spells; and with the gift of discovering mines and hidden treasures. It is not uncommon to see Malay men and women, at the sight of a Binua Pawang, throw themselves on the ground before him.—*Journ. Ind. Arch. Vol. III. No. 2 Feb. 1849, page 155.*

(2163) PEARLS. On the Natural and Artificial production of Pearls in China. By F. Hague, H. B. M. Consul at Ningpo. (*Read 17th December 1853.*)

Mankind had probably no sooner taken to the use of oysters as food than pearls were discovered and at no period could they be so rude as not to prize the beautiful animal gem: hence in the most ancient records which have come down to us we find the pearl enumerated amongst precious articles. In China, so early as twenty two and a half centuries before our era, pearls are enumerated as tribute or tax: and at a later

period they are mentioned in the Rh-ya (the most ancient of dictionaries compiled more than ten centuries before our era) as precious products of the western part of the empire. They are also mentioned as ornaments and as amulets against fire, &c. With their theory of the devil's power, the Chinese are never perplexed: concerning the nature of any object it is sufficient to state that they are the female essence of the male principle. It is but fair to add that when Western naturalists adhering to Pliny taught that the oyster produced pearls from the heavenly dew on which it fed, a Chinese writer plainly states that pearls are the result of discoriation in the shell. Fresh water pearls were first in use in China, but soon after the commencement of intercourse with the continent of the Indian ocean they doubtless got them from thence in greater abundance. It was very early that official intercourse first took place. The Emperor Wuh (140-86 B. C.) sent to the sea for the purchase of pearls. After the introduction of Buddhism and when intercourse with India became more common, pearls were also frequently referred to in Buddhist writings as "Moni pearls." From one of these Moni pearls, the product of a dragon's tail, sufficient light was emitted to a cockatrice. A strange but not incredible story is given (806 A. C.) of a pearl as large as a pear which retained its lustre only three years, the result doubtless of molecular changes. Amongst the pearls of note is one of Japan as large as a hen's egg of remarkable lustre by night; of another sent to court in the middle of the eight century of extraordinary brightness like that of the moon and of another three inches seven-tenths in circumference which, with several others was sent up from Fokien probably derived from Ceylon. A curious account is recorded of an embassy sent in 1023 A. C. from Shiloch-ayenthoh by the king of Chinlien by his ambassador named Puyah-toil and others with presents of a cap and sancer and of a quantity of true pearls: and thirty or forty years later tribute bearers again came from the same court and solicited that in their audience they might be permitted to follow the customs of their own country which was graciously accorded. On the day appointed the messenger appeared at the door of the audience chamber kneeling and holding a golden tray containing pearls and golden figures of the water lily and on approaching the throne they tossed the contents on the floor before the Emperor which the courtiers instantly swept up and divided. They are noted as the most deferential of people. They must have been from some country which then existed in India or Ceylon or thereabouts. Marco Polo also mentions pearls in his work on China. At what period the Chinese fishing for pearls commenced cannot be ascertained except perhaps by reference to local topographical works which it is very difficult, nay almost impossible,

## PEARLS.

to obtain. One account represents pearls as being found on the coast generally south of Canton. No particulars are given except of the fishery in the department of Lien-chan in the extreme southern part of the empire in the Canton province (Kwantung). On the sea is an island on which there is a pool or lake which the district magistrate annually visits to receive the tribute; personally inspecting the operation: The pearl fishers dive into the lake for pearls. The old shells are opened for pearls. The bottom of this lake is supposed to communicate with the sea—unfathomable in the centre—the crater probably of an extinct volcano; pearls as large as beans sometimes an inch in circumference have been found. The young shells are strung on a bamboo stick and dried in the sun mixed with cassia: then roasted in some medicinal production: they contain pearls as large as millet, thus the womb of the shell is the flesh, either of the large or small kinds. Another account names the district in Lien-chan where the pearl fisheries are conducted. In the sea there is an island with a lake into which the barbarous natives dive for shells: some years they are abundant and in others scarce. There is a myth amongst the fisher-men, of a walled city at the bottom guarded by monsters containing pearls of large size and splendour but which cannot be obtained for fear of the guards; small ones growing outside the city walls like grass being the only ones obtainable. Another writer says, South east of the Too city there is a smooth river with a sea (an island with a lake), Yuenmei river, containing large oysters having pearls. Visited by moonlight fishermen descend into the waters with a basket fastened to their waists: when they can hold their breath no longer they give a signal to be brought up. Voracious fish sometimes attack the divers when the rope floats upwards. Yung-tai-kei when at Canton appointed a Pearl Inspector. The fishers would collect several baskets of sea plants something similar to the willow which they detached from the rocks under water and brought them to the office. On the middle of these bushes were shells which contained pearls. Another writer says the rude sea people at Canton dive for pearl shells and cut them out; they leave their sea vessels in which they live and take to boats and then with a rope about the waist descend into the water; when they require breath they make a signal and are aided up. It is stated that between 1403-25, in consequence of so many of the divers being devoured by the sand fish (shark) or nothing left but their limbs, the fishers contrived an iron rake for gathering shells without diving, but they got a few only. Afterwards they contrived the method now pursued of a dredged or a scoop-like implement one on each side of the boat which as the boats sailed along gathered the shells. The above remarks are gathered

## PEARLS.

from old native authors, but it is not likely that the pearl fishery exists at present at all in China, the places being exhausted as many others have been elsewhere. Were they now in existence they could hardly have escaped the notice of foreigners resident at Canton. These ingenious people were the first to devise methods to imitate the pearl. There is a note that at the commencement of the seventh century pearls were made of a composition of medicine. The art may have been lost or it may be the same as that now employed at and which originated at Canton and which appears to resemble that pursued by the French, who however have carried the art to a very much superior degree of perfection. Feeling much interest as to the method pursued by the Chinese with the Muscle Pearl in the winter of 1851-52 (in conjunction with a friend, Dr. McGowan, an American Physician resident at Ningpo by whose assistance he has been enabled to put together the preceding data, the writer dispatched an intelligent native to Hoochow in the adjacent province about three days journey from Ningpo, where the manufacture of artificial pearls &c. by means of the muscle fish is carried on to a great extent, and he succeeded in obtaining shells shewing the process during the different stages and also some live fish the first ever seen by foreigners. The fish are collected together in April or May and are opened principally by children who put a small bit of bamboo in the orifice: the elders then insert whatever they wish. The foreign substance made use of is composed of brass, bone, pieces of round pebble or mud. When the latter is used it is first well powdered, after which the pitch or juice of a tree is mixed with it to give it solidity. These are put indiscriminately into the fish and require nothing to keep them where they are placed, indeed it would appear that the fish have no power of themselves to reject anything which may be placed in them. After the fish have been operated upon, three spoonfuls of the scales of a fish, well powdered and mixed with water, are put into the smaller ones and five spoonfuls into the larger ones, the pieces of bamboo are then withdrawn and the fish are placed carefully in the ponds at a few inches apart. Some of the ponds being small will hold only about 5000 fish but the larger ponds contain a far greater number. The water in the ponds does not require to be deeper than from three to five feet and in dry seasons water is occasionally worked with them from the canals which intersect the country in every direction for the irrigation of the land. Four or five times each year the ponds are well manured with night soil. The fish are generally taken out of the ponds after ten months, but if allowed to remain a longer time they come to greater perfection, three years being considered the maximum time. Several millions of these

## PEARLS.

shells annually find a market at Hoochow: the price varies considerably, some being worth about a penny the pair while others readily fetch eight pence the pair. The greater portion of the shells are sold to the dealers as they are taken out of the ponds but the Hoochow people prepare some few themselves and the price of each pearl or image ready for use is from one farthing to four pence. The shell is cut through with a fine saw as close to the pearl as possible the bit of shell which remains attached to the pearl is then removed as well as the brass bone or whatever may be inside of it, white wax being substituted and at the extremity a piece of the shell is again placed so as to render the pearl as perfect as possible. There are only a very few pearls of the best description which no doubt arises from the haste in which the Chinese force them upon the market. It is several years since the attention of foreigners at Ningpo was first drawn to the muscle Pearl and previous to the discovery, I as well as others imagined the articles resembling pearls which the wealthy natives wear so prominently on their caps were real and valuable gems. The production of the artificial pearls is quite a trade in the neighbourhood of Hoochow whole villages being engaged in it: indeed it is stated that some 5000 people find a livelihood by these means. The process was first discovered by Ye-jin yang a native of Hoochow. A. D. 1200. 1300. At his death, a large temple was erected to his memory at a place called Seaou-shang about twenty six miles distant from Hoochow. This temple is still kept up and plays are performed there every year to Ye's honor. A book is extant which contains every particular connected with this interesting subject but it could not be purchased. Mention of the art is made in the book of the district and of its producing an important article of commerce. The trade is a monopoly amongst a certain number of villages and families and any other village or family commencing it is required to pay for some plays at Ye's temple and likewise to subscribe something towards the repair of the temple. The Chinese in the south of Canton, also manufacture artificial pearls: the two provinces it is stated having exchanged their secrets many years ago, but the Hoochow people do not succeed very well with the Canton process, and there must be some very great peculiarity in either the climate or fish as it does not appear that the Canton people who are so noted for their perseverance with anything by which they can earn even a trifle have ever succeeded with the Hoochow method. From the circumstance of the trading junks both from the northern and southern provinces buying up all they can meet with in the shops at Ningpo, it would seem as though Hoochow was the only place in China where this trade is pursued.—*Journal of the Royal Asiatic Society of Great Britain and Ireland, Vol. XVI. Part 11, page 280.*

## PERSIAN GULF.

(2164) PEER-I-DUSTAGHEER SAHIB, a Mahomedan Wulee or saint whose tomb is at Baghddad. He is considered the chief of their saints.—*Herk.*

(2165) PEGU. Major Phayre, in July 1856, set down the following as the area and population of the British Province of Pegu.

District.	Area, Sq. M.	Population.
Rangoon. ...	9,800	137,130
Bassein. ...	8,900	128,189
Prome. ...	5,500	70,000
Henzada. ...	2,200	103,775
Toungoo. ...	3,950	34,957
Tharawadee ...	1,950	66,129
Total. ...	32,300	540,180

(2166) PELICANUS INFLATIFRONS. Blyth. A remarkable species of Pelican, was lately living in the menagerie of the Maharaja of Burdwan, in company with specimens of *P. Javanicus* and *P. Crispus*. It is generally similar to *P. Javanicus*, but has the frontal skin curiously inflated, so as to present somewhat the appearance of a largely developed frontal knob of *Anser Cygnoides* only feathered; and a further difference consists in the naked skin of the cheeks and pouch being yellowish-white, whereas in *P. Javanicus* that of the cheeks is deep purplish or livid carneous and of the pouch intense yellow. Mr. Blyth states, if distinct and new, *P. Inflatifrons*. Blyth,—*Jour. B. As. Soc. Nov. 1856.*

(2167) PENARU PALAM MARAM, the Malayala name of a tree. It is used at times by the natives, but is of little value.—*Edye M. and C.*

(2168) PERJI, the Malayala name of a tree which grows to about twelve feet in height, and ten inches in diameter. It is very hard and strong, and is used by the natives for knee and boat timbers; and is ranked among the jungle-woods of the coast.—*Edye M. and C.*

(2169) PERRA MARAM in Malaya, Coia Marm in Tamil, are names of the tree *Psidium Pyriferum* that produces the guava fruit. Its wood is very hard and close grained. This tree grows to about twelve or eighteen feet high, and eight inches in diameter; it is used, in conjunction with the jungle-woods, for inferior purposes, but is generally known as a garden fruit-tree.—*Edye. M. and C.*

(2170) PERSIAN GULF. There are but two winds which prevail in the Persian Gulf, the north-west and south-east, and when the latter sets in, the whole force of the sea is brought to bear directly against the current of the Euphrates, and hence an enormous deposit is effected of the aluvium brought down by the stream, thus barring up its mouth. This deposit, constantly on the increase, progresses, according to Sir Henry Rawlinson, at the rate of a mile in the lapse of

## PHYLLOSCOPUS SIBILATRIX.

thirty-five to forty years. A great city, of which the ruins are to be seen above Mahammerah, was an island in the time of Sennacherib, named Billat, and can be shown to have been still an island in the time of Alexander. At the present time it is sixty miles from the mouth of the river, and a succession of cities can be traced upon the desiccated delta below it, along the river, down to the sea.

(2171) PETROLEUM BEDS. Occur in Assam.

(2172) PERDICINÆ, Genus *Sacfa*, Blyth, *Sakpha* of the Tibetans, T. Hodgsoniæ, Blyth. This handsome species is dedicated to Mrs. Hodgson, whose accurate and tasteful delineations of Himalayan scenery will do much to attract attention to this fine field for scientific research.

The essential characters of the genus or sub-genus are as follows:—

Bill, strong with a heavy overlying upper mandible, scarpd along the cutting edges. Nares subvertical and opening towards the head. Wings and tail longer, and less bowed and gradated, and stronger than in *Perdix*; but not so long or acuminate as in *Lerva*, and about equal to *Francolinus*.

Wings with 3-4-5 quills longest and nearly equal, 1-2 not much gradated: 1st only  $\frac{1}{2}$  inch less than the longest.

Tail 16, rounded, firm.

Tarsi moderate, equal to the longest toe and nail, nude, bi-scaled in front, no spur?

Lateral toes subequal and furnished with the usual basal membrane. Nails blunt, scooped inferiorly and having a salient margin all round: orbits subnude, as in *Arboricola*.

This fine species is denominated *Sakpha* by the Tibetans. It was obtained in the western part of the province of Tsang.

(2173) PHULLAEED. In Nepaul, a kind of oak, the wood of which is in high repute for its strength and durability; the acorns are used medicinally and also serve as food for the pigs.—*Smith's Nepaul*.

(2174) PHYLLOPNEUSTE OCCIPITALIS, This was known from a specimen procured in S. India by Mr. Jerdon.—*Beng. As. Soc. Jour.* No V. of 1854.

(2175) PHYLLOSCOPUS and its immediate affines. *A Monograph of the Indian species of*, By EDWARD BLYTH.

There is no group of birds more difficult to the student of Indian Ornithology, than the very extensive series of small *Bec-fins*, or "Warblers," known to the French as *Pouillots*, and in parts of England by the name of *Pettychaps*. It is exemplified in Europe by the following four well known species.

(2176) *a*. PHYLLOSCOPUS SIBILATRIX;

## PHYLLOSCOPUS TRIVIRGATUS

*Motacilla sibilatrix*. L.: *Sylvia sylvicola*, Latham. Type of SIBILATRIX, Kaup.

• (2177) *b*. PHYLLOSCOPUS BONELLI; *Sylvia Bonelli*, Vieillot: *Sibilatrix Nattereri*. Temminck.

(2178) *c*. PHYLLOSCOPUS TROCHILUS; *Motacilla trochilus*, L.: *Sylvia fitis*, Bechstein: also, according to M. Degland, *Sibilatrix icterina*, Temminck (nec Vieillot); *Sibilatrix flaviventris*, Vieillot; *Sibilatrix angusticauda*, Gerbe; and *Sibilatrix tamarixis*, Crespigny.

(2179) *d*. PHYLLOSCOPUS RUFUS; *Curuea rufa*, Brisson: *Sylvia collybita*, Vieillot; *sibilatrix loquax*, Herbert; and by the older British ornithologists erroneously assigned to *Motacilla hippolais*, L. In addition to these four, in N. Africa, Dr. Ruppell describes

(2180) PHYLLOSCOPUS UMBROVIRENS; *Sylvia umbrovirens*, Ruppell (described but not figured in his *Neuen Wirbelthieren Vogel*, p. 112), from Abyssinia.

(2181) PHYLLOSCOPUS BREVICAUDATUS; *Sylvia brevicaudata*, Ruppell, Atlas, t. 35, from Kordofan.

Another that will probably have to be added to the European fauna is

(2182) PHYLLOSCOPUS BREVIROSTRIS; *Sylvia brevirostris*, Strickland, P. Z. S. 1836, p. 98. Procured at Smyrna. Differs from *Phylloscopus rufus* in its greater size, and from *Phylloscopus trochilus* "in the shortness of the beak, and the dark colour of the legs."

Lastly, two species are briefly described in Dr. Horsfield's catalogue of Javanese birds, *Trans. Lin Soc.* XIII. 156; neither of which can we identify with Indian species: viz,

(2183) PHYLLOSCOPUS JAVANICUS; *Sylvia javanica*, Horsfield: seemingly affined to our *Phylloscopus Magnirostris*. And

(2184) PHYLLOSCOPUS MONTANUS; *Sylvia montana*, Horsfield: apparently affined to our *Phylloscopus tristis*. Of *Phylloscopus montanus*, (Horsf.), the late lamented Hugh E. Strickland mentioned that "the wing is 2 in. long, gradated, with the fifth quill longest."

Mr. Strickland adds, from Java,—

(2185) PHYLLOSCOPUS TRIVIRGATUS; *Sylvia trivirgata*, Temminck; a species referable to Mr. Hodgson's Group *Abrornis*; and it is probable that others of this minor group, from the Archipelago, remain to be described.

In addition to the above, there occurs as an *avis rarissima* in Europe, the common Indian *Motacilla proregulus*, Pallas (*Regulus modestus*, Gould), which strictly appertains to the series under review, has been obtained in Dalmatia and in Britain; while three of the European species have been stated to occur in India, but

at a time when the various Indian *Pouillots* were undescribed and the multiplicity of distinct species of them was unsuspected. As neither of them, however, would appear to have been met with in the country since the numerous Indian species have been recognised, we are led to infer that certain other species were mistaken for them; and it is highly probable that the *Sylvia sibilatrix* of Dr. Royle's list [Note. *Ill. Him. Bot. Introd.* p. lxxvii. In this list are enumerated "*Sylvia sibilatrix*, s. *rufa* (plains), *S. trochilus*, and several species undetermined." It is not probable that either of the names specified is correctly applied; nor certain others in the same list, as especially *Gallus sonneratii*?] refers to our *Phylloscopus nitidus*, and Mr. Gould's *S. trochilus* of W. India (*Proc. Zool. Soc.* 1805, p. 90.) to our *Phylloscopus viridanus*; and perhaps M. Temminck's *S. trochilus* of Japan may likewise prove to refer to some nearly affined species, which he failed to distinguish from the *trochilus* of Europe. [Note. Some Japanese birds which we saw with Mr. Gould, sent by M. Temminck, and identified by him with European species, certainly presented differences more or less marked. We especially remember the Japanese Robin, Jay, and Bullfinch. The last is probably *Pyrrhula griseiventris*, Lafresnaye, *Rev. Zool. de la Soc. Cuv.* 1841, p. 241.—Since this note was penned, we have seen Mr. Gould's figure of the Japanese Bullfinch, in his 'Birds of Asia,' where it is designated *P. orientalis*, Temminck and Schlegel. The Jay, too, is cited by the Prince of Canino as *Garrulus Japonicus*.]

The Indian species have been described under various generic names; and even now it would not appear that systematists are agreed whether to range the accepted typical form from that of *Motacilla trochilus*, L., under *Phyllopneuste* of Meyer (1822), which included also the distinct form of *Mot. hippolais*, L. regarded by Mr. G. R. Gray (in 1841) as typical of *Phyllopneuste*,—or in *Phylloscopus*, Boie (1826), of which *M. trochilus* is cited as typical. In M. Degland's 'Ornithologie Européenne' (1849), *M. hippolais*, L., with three European congeners is referred to *Hippolais*, Brehm (1828), the typical species being termed *Hippolais polyglotta*, (Vieillot); and *M. trochilus* and its congeners are assigned to *Phyllopneuste*. An older name than *Hippolais*, Brehm, occurs, however, in *Ficedula*, Koch (1816), which is adopted by Dr. Rüppell for the *Pouillots*, [*Systematische uebersicht der vogel nord-ost Africka's* (1845), p. 57,] and by Schlegel for both groups; [*Revue Critique des Oiseaux d'Europe* (1844), p. p. XXV—VI.] but it is faulty as implying these birds to be fig-eaters (or *Beccaficos*), whereas all of the series are exclusively insectivorous, and in no way to be confounded with the highly frugivorous *Fauvettes*.

[Note. The four European species described by M. Degland under *Hippolais* are as follows:—

(2186) 1. *Hippolais polyglotta*; *Motacilla hippolais*, L.; *Sylvia polyglotta*, Vieillot: *Hippolais salicaria*, Bonap.

(2187) 2. *Hippolais icterina*; *Sylvia icterina*, Vieillot (nec Temminck): *S. hippolais* apud Temminck, *Manuel*, 2nd edit., (1820).

(2188) 3. *Hippolais olivetorum*; *Sylvia olivetorum*, Strickland.

(2189) 4. *Hippolais elaica*; *Salicaria elaica*, Lindermayer: *Ficedula ambigua*, Schlegel.]

In former papers, Mr. Blyth followed Mr. Gray's arrangement, but with this error, that certain Indian species were assigned to *Phyllopneuste* apud Gray (V. *Hippolais*, Brehm); whereas upon referring to the characters of this genus, as specified by M. Degland, we find that he had misapprehended it, and incline now to suspect that with it should be united the divisions *Culicipeta*, Blyth, and *Abrornis*, Hodgson.

In a series of 22 species actually before us, excluding *Regulus*, we observe that one only, the European *Phylloscopus sibilatrix* (type of *sibilatrix*, Kaup), is remarkable for the comparative great length of its wings; whereof the first primary is minute and the second is nearly as long as the third. In all the rest, the small first primary is considerably less diminutive, and the second is much shorter than the third: the proportions varying, however, to some extent, and the wing being more or less rounded in different species; affording a good differential character in several instances. In general, the wings are shorter and more rounded than in the European *Phyllopneuste trochilus*, but looking to the ensemble of characters, it seems doubtful whether more than three divisions can be retained in the whole series under review. These are *Phylloscopus*, certain species of which (constituting the *Reguloides*, Blyth,) offer a close approximation to *Regulus*, and serve to indicate the true systematic position of that genus,—*Regulus* (which M. Degland and others have arranged near *Parus*),—and *Culicipeta* (including *Abrornis*), which should perhaps be merged in *Phyllopneuste* (V. *Hippolais*). Under these three groups only, we now comprise the following Indian species.

I.—Genus *Phylloscopus*, Boie, apud G. R. Gray. Type *Motacilla trochilus*, L. [Note. A better average type exists in *Phylloscopus rufus*, V. *curruca*, *rufa*, Brisson.]

(2190) PHYLLOSCOPUS RAMA; *Sylvia rama*, Sykes, P. Z. S. 1832, p. 89. There appear to be two races of this bird, differing a little in shade of colour, but in no other particular that we can discern. The bill is rather thicker and the form less slender than in most others of the genus; and together with the colouring, approximate it to *Calamoherpe*, Boie, for a species of which it

## PHYLLOSCOPUS MAGNIROSTRIS.

might be mistaken at first sight; \* but the form of the wings and tail, and general character, sufficiently indicate its true position to be as here arranged.

Length 5 in., by  $7\frac{1}{2}$  in. in alar expanse: wing  $2\frac{3}{8}$  to  $2\frac{1}{2}$  in.; 1st primary  $\frac{9}{16}$  in., the second  $\frac{5}{8}$  in. shorter than the third, which about equals the 4th and 5th: tail  $2\frac{1}{8}$  in.; its outermost feather  $\frac{1}{8}$  in. shorter: bill to gape  $\frac{5}{8}$  in.: tarse  $\frac{3}{4}$  in. Irides dark. Bill dusky above, light caraneous below: legs light brown, tinged with plumbeous on the joints. Plumage, above uniform light greyish-brown; below pale or albescent, passing to white on the chin, middle of belly and vent: lores, continued as a slight streak passing over the eye, and the orbital feathers, pale.

This bird is very common in Lower Bengal during the cold season, upon sandy soil above the tideway of the rivers; haunting babul topes and scattered trees near villages, as well as hedges and bush-jungle. Those of S. India have a slight ferruginous tint throughout; but we can detect no further difference. It would not appear to inhabit the sub-Himalayan region.

\* [Note. We have three Indian species of *Calamohерpe*, all distinct from those of Europe.

(2191) *a. Calamohерpe brunescens*; *Agrobates brunescens*, Jerdon. Very like the European *Calamohерpe arundinaceus* (*Turdus arundinaceus*, L.; *Sylvia turdoides*, Meyer); but easily distinguished by the form of the wing, in which the second or first developed primary is constantly  $\frac{1}{2}$  in. shorter than the next, and the third, fourth, and fifth are subequal.

(2192) *b. Calamohерpe dumetorum*. Blyth, J. A. S. XVIII. 815.

(2193) *c. Calamohерpe agricola*, Jerdon, *Madr. Journ.* XIII, pt. II, p. 131; J. A. S. XIV, 595. This much resembles the European *Calamohерpe salicaria* (*Motacilla salicaria*, Gmelin; *Calamohерpe alnorum*, Brehm; *Mot. arundinacea*, Lightfoot); but is readily distinguished from it, as is also *Calamohерpe dumetorum*, by the same difference in the proportion of the primaries as exists in the species before cited.

The three Indian species of *Calamohерpe* accordingly tend to approximate *Phylloscopus* in the form of the wing, and they have also less aquatic habits than their European congeners.]

(2194) PHYLLOSCOPUS MAGNIROSTRIS. Blyth, J. A. S. XII, 966: *Phyllopneuste indica*, Blyth J. A. S. XIV, 593: *Ph. trochilus*? apud Hodgson, Gray, *Zool. Misc.* 1844, p. 82.

Length 5 to  $5\frac{1}{2}$  in., by  $8\frac{1}{2}$  in. across: wing  $2\frac{5}{8}$  to  $2\frac{3}{4}$  in., its first primary measuring  $\frac{3}{4}$  in., and the second being  $\frac{1}{2}$  in. shorter than the third, which does not quite equal the 4th and 5th: tail 2 to  $2\frac{1}{8}$  in., its two outer feathers on each side very slightly graduating: bill to gape

## PHYLLOSCOPUS AFFINIS.

$\frac{5}{8}$  in.: tarse  $\frac{3}{4}$  in. Irides dusky. Bill dusky plumbeous above, fleshy horn-colour at base of lower mandible. Legs albescent, plumbeous. Plumage, duskyish or infuscated olive-green above, having a faint tinge of tawny, especially on the wings and tail; the medial larger coverts of the wings being tipped with albescent greenish: a narrow but conspicuous pale yellowish supercilium, and the lower ear-coverts are partly of the same hue: under-parts pale; the breast tinged with ashy, mingled with faint yellowish, and the rest of the lower parts are more or less of a pure yellowish-white. The tawny hue of the wings and tail resembles that of the upper parts of the European *Ph. rufus*, whence the name of the latter species.

The species appears to be generally diffused over the country, and we have seen specimens from the eastern coast of the Bay of Bengal, and also one from Chusan. We have been informed that it has a pleasing song.

(2195) PHYLLOSCOPUS LAGUBRIS. Blyth, J. A. S. XII, 668. Length  $4\frac{3}{4}$  to  $4\frac{1}{2}$  in., by  $7\frac{1}{2}$  in. across: wing  $2\frac{1}{2}$  in.; first primary  $\frac{3}{4}$  to  $1\frac{3}{8}$  in., and the 2nd  $\frac{5}{16}$  in. shorter than the third, which does not quite equal the 4th and 5th: tail  $1\frac{7}{8}$  in., subeven. Bill to gape nearly  $\frac{5}{8}$  in. Tarse  $\frac{3}{4}$  in. Irides dusky. Bill dusky above, and also on the medial part of the lower mandible; the rest amber-coloured. Legs pale greenish-dusky. Plumage, above dusky olive-green, nearly as in the last species, but without the tawny shade; also a similar pale yellowish supercilium, and tips to the medial wing-coverts: below albescent, faintly tinged with yellow medially, and laterally with the hue of the flanks.

Common in Lower Bengal during the cold season, and more or less so over the country generally.

(2196) PHYLLOSCOPUS AFFINIS; *Motacilla affinis*, Tickell, J. A. S. II, 576: *Ph. flaveolus*, Blyth, *passim*; *Abrornis xanthogaster*, Hodgson, Gray, *Zool. Misc.* 1844, p. 82. Length  $4\frac{3}{8}$  to  $4\frac{1}{2}$  in., by  $6\frac{1}{2}$  to 7 in. in expanse: wing  $2\frac{1}{8}$  to  $2\frac{3}{8}$  in.; having the 1st primary  $\frac{3}{4}$  in., and the second  $\frac{5}{16}$  in. shorter than the third, which almost equals the 4th and 5th: tail  $1\frac{3}{4}$  to  $1\frac{7}{8}$  in., its outermost and penultimate feathers very slightly graduating: bill to gape  $\frac{1}{2}$  in., or a trifle more: tarse  $\frac{3}{4}$  in. or nearly so. Irides dark. Bill dusky above, amber-coloured below: legs pale brownish-dusky, tinged with yellow; the soles more or less yellowish. Plumage, above fuscous olive-green, with an extremely faint tawny tinge; no pale tips to the medial wing-coverts: supercilia, cheeks and under parts, pale sullied yellow, brightest on the middle of the belly, with a slight tawny tinge in some, and the breast and flanks a little infuscated.

This species might be supposed to be the young of the preceding, in corresponding yellow-

## PHYLLOSCOPUS FUSCATUS.

ish garb to the young of *Ph. trochilus* and *Ph. rufus*; but in minute comparison of freshly killed specimens, they are seen to be distinct. The bill is more feeble, and much more compressed, in *Ph. affinis*; whereas in *Ph. lugubris* it is very little compressed, and the rectal setæ are considerably more developed. The colour of the legs is also very different, being in *lugubris* pale greenish-dusky, while in *affinis* there is a strong tinge of brown. From examination of a great number of specimens, we feel convinced that the colouring here described is permanent. The species is common in Lower Bengal, more so above the tideway of the rivers, and we believe that it is generally distributed over India.

(2197) PHYLLOSCOPUS INDICUS; *Sylvia indica*, Jerdon, *Madr. Journ.* XI, 6: *Phylloscopus griseolus*, Blyth J. A. S. XVI, 443.

Length  $5\frac{1}{4}$  in., by  $7\frac{1}{4}$  in.: wing  $2\frac{5}{8}$  in. having the first primary  $\frac{7}{8}$  in. long, and the second  $\frac{3}{8}$  in. shorter than the third, which equals the sixth, and is scarcely shorter than the fourth and fifth: tail 2 in.: bill to gape  $\frac{5}{16}$  in.: tarse  $\frac{3}{4}$  in. Irides very brown. Bill dusky above, below pale amber, interior of the mouth whitish, with scarcely a tinge of yellow. Tarse externally and the toes above, light brown; internally and beneath, yellow. Plumage, above uniform dull ash-colour, without a tinge of green: supercilia clear pale yellow: lower-parts pale dull yellowish, purer on the middle of the belly, and the rest more or less tinged with dull tawny.

This species appears to be found chiefly in the peninsula of India, and is rare in Lower Bengal.

(2198) PHYLLOSCOPUS FUSCATUS, Blyth, J. A. S. XI, 113. *Phylloscopus brunneus*, Blyth J. A. S. XIV, 591, (the young).

Length 5 to  $5\frac{1}{4}$  in. by  $7\frac{1}{8}$  to  $7\frac{3}{8}$  in.: wing  $2\frac{1}{4}$  to  $2\frac{3}{8}$  in.; having the first primary  $\frac{1\frac{3}{8}}{1\frac{3}{8}}$  to  $\frac{1\frac{5}{8}}{1\frac{5}{8}}$  in., and the second  $\frac{5}{16}$  in. shorter than the third, which equals the 6th and is a little shorter than the 4th and 5th; tail  $2\frac{1}{8}$  in., with its outermost feathers  $\frac{3}{16}$  in. shorter than the middle ones: bill to gape nearly  $\frac{5}{8}$  in.: tarse  $\frac{7}{8}$  in. Irides dark hazel. Bill dusky above, yellowish at base of lower mandible; inside of the mouth rather pale yellow: legs greenish-brown. Plumage, above uniform olive-brown; below albescent, purest on the throat and middle of belly, and weakly tinged with a ferruginous or ruddy hue on the pale supercilia, sides of neck, flanks and lower tail-coverts, and more faintly on the breast; axillaries also weak ferruginous, with the fore-part of the under-surface of the wing; and the primaries are slightly margined with pale rufescent: no trace whatever of a wing-band. The young (*Phylloscopus brunneus*, Blyth, passim,) resemble the adults in colour, but the wings and tail are rather shorter, and the plumage is of somewhat more open texture.

Not rare in Lower Bengal during the cold

## PHYLLOSCOPUS TRISTIS.

season; but commoner, it would seem, to the eastward, and especially in Arakan.

(2199) PHYLLOSCOPUS VIRIDANUS, Blyth J. A. S. XII, 967: [Note. *Phyllopneuste rufa* apud Blyth, J. A. S. XI, 191: and *Ph. affinis*, *Ann. Mag. N. H.* 1843, pt. 2, p.] *Abornis tenuiceps*, Hodgson, Gray, *Zool. Misc.* 1844. p. 83. (Perhaps *Phylloscopus trochilus*, W. India apud Gould).

Length  $4\frac{3}{4}$  to  $5\frac{1}{8}$  in., by  $7\frac{1}{4}$  to  $7\frac{1}{2}$  in.: wing  $2\frac{1}{4}$  to  $2\frac{1}{2}$  in.: its first primary  $\frac{5}{8}$  to  $\frac{3}{4}$  in., and the second  $\frac{1}{4}$  in. shorter than the third, which equals the fourth and fifth; tail  $1\frac{3}{4}$  to 2 in. Bill to gape nearly  $\frac{5}{8}$  in.: tarse  $\frac{1\frac{1}{8}}{1\frac{1}{8}}$  to  $\frac{3}{4}$  in. Irides dusky. Bill dusky horn-colour above, the under mandible yellowish except towards tip. Legs pale greenish-plumbeous. Plumage, above light dull olive-green, beneath greenish-albescent: a pale yellow streak over the eye; and a slight whitish bar on the wing, formed by the tips of its larger coverts.

The commonest species of the genus in Lower Bengal; and we believe generally diffused. The only sound we have heard it utter is a faint *tiss-yip* frequently repeated; but never a number of times in continuous succession, like the much louder *tsih tseh* of the European *Ph. rufus*.

(2200) PHYLLOSCOPUS NITIDUS, Blyth, J. A. S. XII, 965: *Muscicapa nitida* (?), Latham, Franklin: *Sylvia hippolais* apud Jerdon, *Madras Journ.* XI, 6; *Hippolais Swainsoni*, Hodgson, Gray, *Zool. Misc.* 1844, p. 82. (Probably *Sylvia sibilatrix* of Royle's list.)

Length  $4\frac{1}{2}$  to  $4\frac{3}{4}$  in., by  $7\frac{3}{8}$  to  $7\frac{1}{2}$  in. across: wing  $2\frac{3}{8}$  to  $2\frac{5}{8}$  in.; having the first primary  $\frac{9}{16}$  to  $\frac{5}{8}$  in., and the second  $\frac{3}{8}$  in. shorter than the third, which equals the fourth and exceeds the fifth: tail  $1\frac{7}{8}$  to 2 in.: bill to gape  $\frac{5}{8}$  in.; and tarse  $\frac{3}{4}$  in. Irides dark. Bill caraneous dusky, the lower mandible pale; and legs light brownish, tinged with yellow on the toes. Plumage, above of a much livelier green than in any of the preceding, resembling that of the European *Ph. sibilatrix*; below unsullied pale yellowish, brightest about the breast; and there is a pale wing-band, formed by the tips of the larger coverts of the secondaries.

This pretty species appears to be very generally distributed, but is somewhat rare in Lower Bengal.

(2201) PHYLLOSCOPUS TRISTIS. Blyth, J. A. S. XII, 966. *Sylvia trochilus* apud Jerdon, *Madr. Journ.* XI, 6.

Length  $4\frac{1}{2}$  to 5 in.,  $6\frac{1}{2}$  to  $6\frac{7}{8}$  in.; of wing  $2\frac{1}{8}$  to  $2\frac{1}{2}$  in.; the first primary  $\frac{3}{4}$  in. (in large specimens), and the second  $\frac{1}{4}$  in. shorter than the third, which equals the fourth and fifth: tail  $1\frac{3}{4}$  to 2 in.: bill to gape  $\frac{1}{2}$  in.; and tarse  $\frac{9}{16}$  to  $\frac{3}{4}$  in. Irides dark. Bill blackish tinged with yellow at base of lower mandible; and gape also yellow: legs dull black. Plumage, above uniform dull

## PHYLLOSCOPUS TROCHILOIDES

brown: below albescent, with a faint tinge of ruddy or ferruginous on the pale supercilia, sides of neck, breast and flanks and no tinge of yellow except on the axillaries and fore-part of the wing underneath, which are almost pure light yellow. Bill small and slender.

A common species, and generally diffused. Once observed in great abundance, together with *Calamoherpe agricola*, haunting low bushes near the Calcutta salt-water lake.

(2202) PHYLLOSCOPUS OCCIPITALIS; *Phyllopneuste occipitalis*, Jerdon, Blyth, J. A. S. XIV, 593.

Length  $4\frac{3}{4}$  in.: of wing  $2\frac{5}{8}$  in.; the first primary  $\frac{3}{4}$  in., and the second  $\frac{5}{16}$  in. shorter than the third, which nearly or quite equals the fourth and fifth: tail 2 in., even or squared. Bill to gape  $\frac{5}{8}$  in. Tarse  $\frac{1}{16}$  in. Alar and caudal feathers unusually firm. Bill light dusky above, pale below: legs pale. Plumage, above mingled green and ashy, the latter prevailing on the back, the former on the rump, wings and tail; crown dusky, with whitish supercilia, and a conspicuous pale medial line, broader and tinged with yellow at the occiput: a slight but distinct yellowish-albescent wing-band; the fore-part of the wing brightish green; and its margin, with the axillaries, pure light yellow. Lower-parts albescent, mingled with yellowish, and very faintly tinged with ruddy. Inner webs of the three outer tail feathers on each side narrowly bordered with white, the ante-penultimate less so.

This pretty species we have only seen from the Deyra Doon and from S. India. In colouring, it approximates the groups *Reguloides* and *Abrornis*; but the remarkable firmness of its wings and tail is peculiar, and prohibitive of its association with either.

The next three species (constituting the subgroup *Reguloides*, Blyth,) have, like the last, a pale medial streak on the crown, and they greatly approximate the genus *REGULUS* in figure and proportions, and even in colouring (minus the developed crest); but their habits are those of other PHYLLOSCOPI.

(2203) PHYLLOSCOPUS TROCHILOIDES; *Acanthiza trochiloides*, Sundevall (1837): *Phyllopneuste reguloides*, Blyth, J. A. S. XI, 191, XII, 963 (nec *Reguloides* apud Hodgson).

Length of a male  $4\frac{7}{8}$  in., by  $7\frac{1}{4}$  in.: wing  $2\frac{1}{2}$  in.; its first primary  $\frac{1}{16}$  in., and the second  $\frac{3}{8}$  in. shorter than the third, which equals the fifth and is a little shorter than the fourth; but, in some, those three are equal: tail  $1\frac{7}{8}$  in., even. Bill to gape  $\frac{5}{8}$  in., or nearly so. Tarse  $1\frac{1}{16}$  in. Length of a female  $4\frac{1}{2}$  by  $6\frac{7}{8}$  in.; wing  $2\frac{3}{8}$  in.; and tail  $1\frac{3}{4}$  in. Irides dark. Upper mandible dusky, the lower yellow: and legs yellowish-brown tinged with plumbeous. Plumage, above dull green, a little infuscated, with two conspicuous yellowish-white bars on the wing, formed by the

## PHYLLOSCOPUS CHLORONOTUS.

tips of the greater and lesser coverts: below albescent-greenish, a little tinged with yellow: a broad yellowish-white or pale yellow supercilium; and above this a broad dusky band, leaving the middle line of the crown dull green like the back, but paling at the occiput; below the supercilium the colour is also dusky: axillaries, with the fore-part of the wing underneath yellow; and the outermost and penultimate tail-feathers have a narrow whitish margin to their inner web.

Inhabits the sub-Himalayas, and visits Lower Bengal in some abundance during the cold season. We have obtained one so late as March 15th in the vicinity of Calcutta.

(2204) PHYLLOSCOPUS PROREGULUS; *Motacilla proregulus*, Pallas: *Regulus modestus*, Gould; and, in abraded plumage, *R. inornatus*, Blyth, J. A. S. XI, 19, and *Phylloscopus montanus*, Hutton, Blyth, *Catal.* No. 1105: *Phyllopneuste nitidus*, Hodgson, G. R. Gray.

Length generally about 4 to  $4\frac{1}{4}$  in., by 6 to  $6\frac{1}{2}$  in. across: wing  $2\frac{2}{8}$  in. its first primary  $\frac{1}{2}$  in., [Note. In one only, of several specimens,  $\frac{5}{8}$  in.] and the second not  $\frac{5}{16}$  in. shorter than the third, which exceeds the sixth, and nearly or quite (in different species) equals the fourth and fifth: tail  $1\frac{1}{2}$  to  $1\frac{1}{4}$  in., even. An unusually large specimen measured  $4\frac{1}{2}$  by 7 in.; wing  $2\frac{1}{4}$  in.: tail  $1\frac{3}{4}$  in. Bill to gape nearly  $\frac{5}{8}$  in.: tarse  $\frac{1}{16}$  in. Irides dark, upper mandible dusky, the lower yellow except at tip; and legs rather pale brown, without any plumbeous tinge. Bill nearly as much compressed as in *Regulus*. Plumage, above olive-green, brightest on the rump, wings and tail: crown dusky, with a pale mesial line, sometimes well defined, but in new plumage not very distinct; and in much worn or abraded plumage, it often disappears altogether, and the upper-parts are then dingy greyish-brown, with scarcely a tinge of green: two conspicuous yellowish-white bars on the wing, the hinder more broad; and behind this is a dark patch, corresponding to the black seen in *Regulus*: tertiaries conspicuously margined with whitish (as more or less in *Regulus*), and secondaries and some of the primaries slightly tipped with the same: axillaries, with the fore-part of the wing underneath, pale yellow: supercilia and lower parts greenish-albescent.

Common in Lower Bengal, where a few perhaps breed; but the great majority retire to the mountains for that purpose. [Note. A reputed nest, taken near Calcutta, is described J. A. S. XII, note to p. 965.] As an exceedingly great rarity, it has been met with in Dalmatia and in England. Habits as in other species of *Phylloscopus*, and not (as in *Regulus*) gregarious: song-note nearly similar to that of *Phylloscopus sibilatrix* but considerably weaker.

(2205) PHYLLOSCOPUS CHLORONOTUS;

## PHYLLOSCOPUS.

*Abornis chloronotus*, Hodgson, Gray's *Zool. Misc.* p. 82; G. R. Gray, 'Appendix to catalogue specimens presented by Mr. Hodgson to the British Museum,' p. 152; *V. Regulus modestus* apud Hodgson.

Resembles the last, but is smaller, with bill conspicuously shorter and darker-coloured, and the rump pale canary-yellow, strongly contrasting with the hue of the back; the median coronal line much more conspicuous, and the pale margins of the tertiaries less so. Its size is that of the European *Regulus cristatus*.

Length  $3\frac{1}{2}$  in., or a trifle more: wing  $1\frac{7}{8}$  to 2 in.; its first primary  $\frac{9}{16}$  in., the second  $\frac{1}{2}$  in. shorter than the third, which does not equal the fourth and fifth. Bill to gape about  $\frac{1}{2}$  in., and tarse  $\frac{5}{8}$  in.: tail  $1\frac{1}{4}$  in. to  $1\frac{3}{8}$  in. Upper mandible blackish, the lower pale except towards tip. Legs pale. In other respects like the last, from which it is at once distinguished by its pale pure yellow rump.

This minute species appears to be peculiar to the sub-Himalayan region, where extensively distributed.

Genus *Regulus*, (antiq.) Cuvier.

Capt. Hutton states that both *R. ignicapillus* and *R. cristatus* of Europe inhabit the N. W. Himalaya. We have seen only a single male specimen, procured by Capt. Thomas at Simla; and this perfectly resembles *R. cristatus*, except in being considerably larger, and the fine flame-coloured interior crest would seem to be more developed. Length of wing  $2\frac{3}{8}$  in., and of tail  $1\frac{1}{2}$  in. In several British specimens of *R. cristatus*, the corresponding measurements are 2 in., and  $1\frac{3}{8}$  in., with the rest in proportion. Should this difference in size prove constant, the race might be denominated *R. Himalayensis*; requiring, however, to be first minutely compared with the N. American *R. satrapa*, Lichtenstein (*V. tricolor*, Jardine). Mr. Hodgson would not appear to have met with a true *Regulus* in Nepal.

(2206) Genus *Culicipeta*, Blyth, J. A. S. XII, 968

"General structure of *Phylloscopus*, but having a narrow Flycatcher's bill and armature of rictus, the ridge of the upper mandible angulated, and the breadth of the bill evenly attenuating." Such are the characters of the first or typical species, to which may be added that the claws, especially that of the hind-toe, are longer and less curved. In other species, however, the form grades to that of *Phylloscopus*; but there is a general and marked resemblance of colouring throughout the series, indicative of their unity as a group, and which would help to separate it from the European type *Phyllopneuste* (*V. Hippolais*). In general, the upper-parts are green, the lower bright yellow wholly or in part, and the crown exhibits the colouring (variously modified) of *Phylloscopus occipitalis* and of the subgroup *Reguloides*; while the two or three outer tail-feathers are, in most of the species, largely

## PHYLLOSCOPUS.

marked with white on the inner web. Their habits appear to be quite similar to those of the *Phylloscopi*.

(2207) *Culicipeta Burkii*; *Sylvia Burkii*, Burton, P. Z. S. 1835, p. 153: *Acanthiza arrogans*, Sundeval (1837); *Cryptolopha auricapilla*, Swainson, 2 $\frac{1}{4}$  Centen. (1837): *Muscicapa bilineata*, Lesson, *Rev. Zool. de la Soc. Cuv.* 1839, p. 104.

Length  $4\frac{3}{8}$  by  $6\frac{1}{2}$  in.: wing  $2\frac{1}{4}$  in.; its first primary  $\frac{3}{4}$  in., and the second  $\frac{3}{8}$  in. shorter than the third, which equals the sixth or seventh (in different specimens), and is rather shorter than the intervening two or three: tail  $1\frac{3}{4}$  in.: bill to gape exceeding  $\frac{1}{2}$  in.; and tarse  $\frac{1}{2}$  in. Irides dark. Bill dusky above; underneath, with the legs, pale amber or brownish-yellow, darker on toes. Plumage, above bright yellowish olive-green; below full siskin-yellow throughout; the cheeks and sides of neck intermediate: over each eye a broad black streak reaching to the occiput, leaving the middle of the head greenish, slightly flanked with ash-grey: tail dusky, its middle feathers margined with the hue of the back, and the inner web of the outermost white nearly throughout, as also the terminal half of that of the next. Some have a light yellowish wing-band, which in others is barely indicated.

This pretty little bird is not uncommon in Lower Bengal during the cold season, and like the rest of its tribe retires to the sub-Himalayan region to breed. Its bill has more decidedly the Flycatcher form than in any of the following.

(2208) *Culicipeta Cantator*; *Motacilla cantator*, Tickell, J. A. S. II, 576: *O. schisticeps*, Hodgson, Gray's *Zool. Misc.* 1844, p. 82; G. R. Gray, 'Appendix to catalogue of specimens presented by Mr. Hodgson to the British Museum,' p. 153.

Length  $4\frac{1}{4}$  in., by  $6\frac{3}{8}$  in. expanse: wing  $2\frac{1}{4}$  inches; with primaries as in *C. Burkii*: tail  $1\frac{3}{4}$  in. Bill to gape nearly  $\frac{5}{8}$  in.; and tarse  $\frac{5}{8}$  in. Irides dark. Bill light dusky above, amber-coloured below: legs light yellowish-carneous, with a leaden tinge. Plumage, bright olive-green above, yellower on the wings and tail: throat, cheeks, supercilia, lower tail-coverts, and margin of wing, bright yellow; the belly and flanks greyish-white: greater wing-coverts tipped with pale yellow, forming a slight bar on the wing: on each side of the crown a broad black band; and an intermediate narrower greenish one, becoming yellower upon the occiput: upper tertiaries very slightly margined at the tips with yellowish-white; and the tail-feathers have a narrow yellowish-white internal border.

This pretty species is rare in Lower Bengal, becoming commoner to the westward. The bill is narrower and the rictal setæ are less developed, while the claws (especially that of the hind toe) are shorter and more curved, than in *C. Burkii*.

## PHYLLOSCOPUS

(2209) *Culicipeta Pulchra*; *Abrornis pulcher*, Hodgson, Blyth, J. A. S. XIV, 592; *Abr. erochroa* (?), Hodgson, Gray, *Zool. Misc.* 1844 p. 82 (undescribed); G. R. Gray, Appendix to catalogue, p. 152.

Length  $4\frac{1}{4}$  in., of wing  $2\frac{1}{8}$  in., with primaries as in *C. Burkii*; tail  $1\frac{3}{8}$  in.; bill to gape  $\frac{1}{2}$  in., and tarse nearly  $\frac{3}{8}$  in. Bill dusky above, below yellow or amber coloured; and tarse pale. Plumage, above dull olive-green, brighter on the rump and margins of the wing and tail-feathers, those of the primaries yellowish, and a pale rufescent bar across the wing: two broad black streaks on the crown, and between them a dull greenish streak flanked with ashy: supercilia also dull green; but the orbital feathers are yellow; and the entire under-parts are pale dull yellow, or albescent-yellowish, becoming of a deeper yellow on the belly and lower tail-coverts: tail having its three outer feathers wholly white, save the terminal half of their outer web, together with the tip of the inner web of the ante-penultimate and slightly of the penultimate.

Inhabits the Nepal and Sikim Himalaya. [Note. Mr. G. R. Gray suggests that this may be the young of his *Abr. erochroa*, Hodgson, which he thus describes:

"Length 5 in.; bill from gape  $\frac{1}{2}$  in.; tarse  $\frac{3}{8}$  in.; wings under  $2\frac{1}{2}$  in. Upper surface olive-green; a streak over each eye from the nostrils, under surface and lower part of back, yellowish white, brightest on the back [rump?] and vent: wings with the tips of the greater coverts broadly margined with rufous-white: quills brownish black, narrowly margined with yellowish-green: tail slaty-brown, margined with yellowish-green, the outer feathers principally white."

We suspect that this description merely refers to a fine specimen of *C. pulchra*; and may remark that the present is the only species of the series of which the Society possesses but an indifferent specimen. Of the rest, *C. castaneoceph* we have never seen; but all of the others, save four, we here describe from recent specimens shot near Calcutta! The four exceptions are—*Phylloscopus occipitalis*, and *Ph. chloronotus*, and the two *Culicipeta* which next follow; and to these may be added the *Regulus*.

(2210) *Culicipeta schisticeps*; *Abrornis schisticeps*, Hodgson, Blyth, J. A. S. XIV, 592; *Phyllopneuste xanthoschistos*, Hodgson, Gray, *Zool. Misc.* 1844, p. 82. (undescribed); G. R. Gray, 'Appendix to Catalogue' p. 151.

Length  $4\frac{1}{4}$  in.; of wing  $2\frac{1}{4}$  in., with primaries as in *C. Burkii*; tail  $1\frac{5}{8}$  in.; bill to gape  $\frac{5}{8}$  in.; and tarse  $\frac{3}{8}$  in. Bill dusky above, below amber coloured; and feet apparently pale brownish plumbeous. Plumage, above pale ashy, passing to greenish-yellow on the rump, wings and tail: below, with the cheeks and lower half of the car-coverts, wholly bright yellow: whitish-grey supercilium and narrow medial streak across the

## PHYLLOSCOPUS

crown, and two broad ill-defined lateral streaks of rather a more dusky grey than that of the back: outermost and penultimate tail-feathers only, white on their inner webs. The young have looser plumage and all the colours less intense.

This appears to be very common throughout the sub-Himalayan territories, and is likewise met with in Arakan; but it appears never to descend from the hills. According to Capt Hutton, it is a common species at 5000 ft. elevation, and commences building in March. The nest would appear to resemble those of *Phylloscopus trochilus* and *Ph. rufus*. Eggs spotless white. Vide Hutton, in J. A. S. XVII, pt. II, p. 688.

(2211) *Culicipeta polio-genys*, Blyth, J. A. S. XVI, 441.

Length  $4\frac{1}{4}$  in.: of wing  $2\frac{1}{8}$  in., with the outermost primary  $\frac{5}{8}$  in. long, the second exceeding it by  $\frac{1}{16}$  in., and the third  $\frac{1}{8}$  in. shorter than the fourth, which equals the fifth and sixth: tail  $1\frac{5}{8}$  in.: bill to gape  $\frac{9}{16}$  in.; and tarse  $\frac{5}{8}$  in. Bill dusky above, yellow or amber-coloured below. Legs pale. Plumage, above dark olive-green, slightly yellowish on rump, with a conspicuous narrow yellowish-white wing-band: crown and ear-coverts dusky-grey, with blackish coronal bands; the chin, and feathers proceeding from the base of the lower mandible, greyish-white: rest of the lower-parts bright yellow: tail with its three outer feathers white on the inner web, as in *C. pulchra*.

We have only seen this well marked species from Sikim. It might be mistaken for the preceding on a very superficial view; but besides the differences in the details of colouring, its wings are much more rounded and the bill is somewhat less compressed.

(2212) *Culicipeta Castaneoceph*; *Abrornis castaniceps*, Hodgson, Blyth, J. A. S. XIV, 593; *Abr. castaneoceph*, H., Gray, *Zool. Misc.* 1844, p. 82; G. R. Gray, 'Appendix to Catalogue,' p. 152.

"Length  $4\frac{1}{4}$  in.: wing nearly  $2\frac{1}{4}$  in.: bill to gape above  $\frac{5}{8}$  in.: tarse  $\frac{5}{8}$  in. Upper surface olive-green: front and top of head, pale rufous-chestnut; hind-head and nape greyish-slate. Lower part of back and abdomen bright yellow: throat white: wings and tail brownish-black, margined with yellowish-green: greater coverts of the wings tipped with yellow, forming two bands."—G. R. Gray.

"Above vernal green: belly, vent, and croup, deep yellow. Chin to belly white, passing laterally to soft plumbeous. Top of head chestnut, bounded by black to sides. Bill and legs pale. Length 4 in.: wing  $1\frac{1}{8}$  in.: tail  $1\frac{5}{8}$  in.: bill to forehead  $\frac{3}{8}$  in.: tarse  $\frac{3}{4}$  in."—Hodgson.

Procured by Mr. Hodgson in Nepal. We have never seen a specimen.

Finally, may be noticed a Javanese species of this group.

(2213) *Culicipeta trivirgata*; *sylvia trivirgata*,

*gatus*, Strickland, figured and described in Sir W. Jardine's 'Contributions to Ornithology,' November, 1849.

"Length 4 in.; of wing 2 in. 2 l.; middle tail-feathers 1 in. 8 l.; outermost  $1\frac{1}{2}$  in.; bill to gape 5-1: tarse 7-1.

"In plumage, it greatly resembles the broader-billed but closely allied *C. Burkei* of India. Middle of crown olive-yellow, which occupies the inner webs of the feathers, the outer webs being deep fuscous, nearly black, with an olive tinge, forming a broad dark stripe on each side of the crown: between this and the eye is a superciliary streak of clear yellow: a streak of fuscous passes through the eye; the cheeks, throat, and lower-parts are bright yellow, with an olive tinge; back and wings yellowish-olive: beak horn-coloured, the base of lower mandible pale; and legs brown.

"Inhabits the island of Java."—*Strickland*.

(2214) PIDDINGTON, H., long Coroner in Calcutta: and well known for his numerous contributions to the literature of storms.

(2215) PINDALOO (or in Tamil) is the root of a tree resembling *Ricinus communis*. This is boiled and eaten by common people.

(2216) PINDUR AND KUPHINEE, two rivers in the Kemaon Himalayas, remarkable for the glaciers which occur in them.

(2217) PINJRAPOLE, or Hospital for Animals. The Jains are the great protectors of animal life. They, together with the Buddhists, are pre-eminently tender on this point, not only on the score of humanity, but from their belief in the doctrine of metempsychosis which teaches them to regard the brutes as of their own kin, the tenements not improbably of the souls of their ancestors. The celebrated King Asoka, who flourished about 250 years before Christ, was the first Hindoo sovereign known to have favoured the tenets of the Jains. His capital was Palibothra, at the junction of the Soane and Ganges. The inscription on the palaces of Delhi and Allahabad, on the rocks in Affghanistan and Girnor in Cutch, refer to the events of his reign. On one of these tablets, Asoka proclaims, that though until then hundreds of thousands of animals had been killed daily for the Royal Kitchen, from thenceforth the practice should be discontinued, as he had become religious. On another it is proclaimed that throughout his dominions, trees for the shade and shelter of men and animals, and wholesome and nutritious vegetables for their consumption shall be cultivated, it is considered probable that the Jains and Buddhists set their faces against animals suffering, as a contrast to the cruelties at the time practised by the Brahmins, and that they to some extent succeeded in shaming them down. It appears from the Ramayana that the

Brahmins of those days made offerings not only of flowers and plants but of slaughtered horses, hogs and sheep; the sacred cow herself being occasionally offered on the altar. At their feasts both butcher meat and intoxicating liquors were freely indulged in. The Brahmin hermit Bhadravaja gave a magnificent entertainment at Allahabad to Charat and his army, where venison, the flesh of the wild boar, mutton, peacocks and partridges with abundance of strong drink, furnished forth the repast. Menu considers the feast in honour of a dead relation incomplete unless where animal food is present, we have no authoritative information as to when the present absurd system crept in: that it is not countenanced by the sacred books of the Hindoos or the customs of antiquity and is a matter comparatively of yesterday is apparent. We are still more in the dark as to the introduction of hospitals for aged and diseased animals. The first we find described is that at Surat of which Ovington gives an account as he saw it in 1689, Hamilton describes it as he saw it in 1772, Heber speaks of that at Broach in 1824. There is nothing that can be adduced in their support either from the sacred works of the Hindoos, the Asoka productions or the institutes of Menu, more than may be inferred from the proverbs of Solomon that "the merciful man is merciful to his own beast." The homage to brute animals originally confined to the Jains and Buddhists, and not even making its appearance amongst them until a comparatively recent period of their history slowly extended itself amongst the Brahmins, and within almost the present generation has infected the Parsees. This comparatively enterprising and enlightened race, so far from being exempt from the degrading superstitions of the Hindoos as has been asserted, seem to have picked up some rags from the superstition of every sect and denomination with which they have come in contact, and patched it on to their own comparatively simple creed. The superstition of the banians, like themselves a great trading community, seems to have been peculiarly attractive to them, and the Pinjrapole accordingly being their pet institution, speedily secured the sympathies of the Zoroastrians.

We confess ourselves very imperfectly informed as to the origin of this most extraordinary form of the faith. It is said that in the reign of the emperor Acbar, 300 years ago, a pious married pair from the Malabar Coast resolved on making a pilgrimage to Benares. When their journey was near an end, the wife was taken in travail, and a man-child was born to her; unable to carry him on, they left him one evening behind them on the moor. Next day the grass was found blazing everywhere around, but the infant was lively and unburnt, the blaze refused to approach him. He was taken charge of by the priests and pronounced at once a child from heaven, the

offspring of the deity. The boy waxed and grew, and shewed an early aptitude for knowledge and when he reached the age of manhood visited the various shrines, castles, and courts around, preaching a form of faith altogether new, specially inculcating tenderness to, and care of animal life. He was the first Maharaja of the Banians. There are about two hundred now alive who claim direct descent from him and are believed by their worshippers, incarnations of the deity. They exercise the most absolute authority both spiritual and temporal over their votaries, who bow with the most abject submission to their behests. If there be any truth in the pamphlet lately published regarding them, their lives and conversation are scarcely such as becomes the heaven descended.

The Bombay Pinjrapole owes its origin as much to the parsee worship of sacred dogs as to the superstitions of the Jains. In 1813, the dogs running wild and masterless in the street had become so intolerable a nuisance that an order was issued for killing them, and the result of this was a succession of street rows and disturbances betwixt the dog-destroyers and dog-worshippers, which led the latter to offer a sum of money for each mangy cur that was released from durance and made over to them. Some 30,000 or 40,000, of these canine incarnations of the deity, are in this way annually packed off, the bulk of them being sent to an island near the mouth of the Taptee to starve, or to worry or infect each other. So cruel are the tender mercies of the wicked and superstitious.

Great expense was incurred on this account, and as the funds began to diminish from failing zeal, Motichund Amerchund, the great Jain merchant, and partner of Sir Jamsetjee Jejeeboy exerted himself and obtained an agreement on the 18th October 1834 from Shree Gosainjee Maharaja, and Setts of the Hindoos, Parsees, and others by which they bound themselves to raise taxes on opium, cotton, sugar, bills of exchange, and pearls "that the lives of a great many animals may be saved, which is an act of great charity," the Shrawuks, or Jains agreed to raise a fund amongst themselves for the required ground and building, the rates are collected and sent yearly to the managers appointed, namely, Bomanjee Hornusjee Wadiajee, Sir Jamsetjee Jejeebhoy, Motichund Amerchund, Vukutchund Khooshalehund. The agreement signed by about 450 merchants, contains a clause stating that any excess of the funds may be applied to such charitable objects as may be approved of by the trustees. As there are now about seven lacs of rupees (£70,000), in excess, here is an ample fund for the extension of education or for a thousand purposes directly tending to elevate the moral and intellectual condition of the country. Whilst the Bombay pinjrapole was under the vigilant superintendence of our Parsee

Baronet, the funds poured amply in and the institution was most carefully conducted. Since 1851, the place has become a sink of animal and moral corruption. Prices on commodities, like other prices, fall all ultimately on the consumers. The Lancashire Cotton-spinners are not perhaps aware that from their pockets are drawn the means of supporting one of the most filthy and disgusting establishments for the torture of brute beasts mind of man or fiend can conceive.

It is chiefly from the date of its wealth that the Bombay institution has become a nuisance and though we are disposed to overlook all and every thing in our great Parsee Baronet, in consideration of the darkness and ignorance of the age in which he was brought up, it will never do for his kinsmen, still less for his descendants, to be presented to royalty, or to the Baronetage of England, as worshippers of unclean brute beasts, the keepers of knackers yards or mangy dog kennels. The existence of the pinjrapole is of itself enough to show the immeasurable distance that intervenes between those who delight in the self-assumed designation of the "Saxons of the East" and their rulers, the Saxons of the West.

We have already so minutely described the pinjrapole that we need not further refer to the filthy, disease-begetting and life-shortening nuisance, than to advert to how fearfully it fails to fulfil any one of the ends it professes to aspire after. To the horse, the ox, the goat, the sheep and the dog more especially the first and the last, fresh air and exercise are indispensable, not only to health and enjoyment, but to existence.

"He is a hunter of the hills, to him confinement is a curse, and followed by the worst of ills."

The noble beast who probably has never once within his life been tied up for forty-eight hours on end, whose master daily even and morn, when there was no work for him to do, saw that he had air and exercise—is, from the day that he enters the pinjrapole, to that when his dead carcase is dragged out of it, pinned down to one spot as firmly and irrecoverably as is the insect in the cabinet of the entomologist. Better die a hundred deaths at once than thus be tortured, and slain by inches. The cattle, sheep and goats fare but little better; the dogs are infinitely worse off than the horse: it not unfrequently happens: that animals which have been sent there by mistake, are recovered by their owners, a single hour in the kennels sends them back covered with vermin, and infected with the most loathsome diseases. Lions, tigers, panthers, and other carnivora are occasionally kept in the pinjrapole; it is forgotten that for every day that one of these is kept alive, one sheep or goat must die to feed him. A butcher sometimes receives a large sum

## PINEAPPLE FIBRES.

for abstaining from the slaughter of sheep or kine. The man pockets the money and keeps his bargain. As the market must be supplied the number spared at one shop or house is made up next door. The precept outwardly attended to in the letter is violated at every turn we take in spirit.

Yet the remedy is singularly easy, the pinjrapole has some £70,000 in the treasury. Let them buy up and wall in a square mile of ground in some of the adjoining islands or on the mainland where both fresh and salt water are available, and give the poor brutes they pretend to preserve after their natural term of existence is ended, a chance of living and of enjoying that measure of peace and comfort their circumstances permit.

We trust these things will be taken into consideration by the natives who worship the pigeon, the cow and the dog, and that they will cease endangering the lives of their fellow creatures before force is employed against them. The first duty of the Municipal Commissioners is to see to the health of the community: whatever is incompatible with this must be put down and speedily. They are armed with unlimited power by the law, though force is the last thing they would dream of resorting to so long as any hope remained of the influence of persuasion. When natives ask to be put on a footing with Europeans, let them be met with the single word "pinjrapole" and that should put them down.—*Bombay Standard*. 1858.

(2218) PINEAPPLE FIBRES. At Singapore, the process of extracting and bleaching the fibres is exceedingly simple. The first step is to remove the fleshy or succulent side of the leaf. A Chinese, astride on a narrow stool, extends on it, in front of him, a pineapple leaf, one end of which is kept firm by being placed beneath a small bundle of cloth on which he sits. He then with a kind of two handled plane made of bamboo removes the succulent matter. Another man receives the leaves as they are planed, and with his thumb nail loosens and gathers the fibres about the middle of the leaf, which enables him by one effort to detach the whole of them from the outer skin. The fibres are next steeped in water for some time, after which they are washed in order to free them from the matter that still adheres and binds them together. They are now laid out to dry and bleach on rude frames of split bamboo. The process of steeping, washing, and exposing to the sun is repeated for some days until the fibres are considered to be properly bleached. Without further preparation they are sent into town for exportation to China.

Nearly all the islands near Singapore are more or less planted with pine-apples, which, at a rough estimate, cover an extent of two thousand acres. The enormous quantity of leaves that are annu-

## PINUS GERARDIANA.

ally suffered to putrify on the ground would supply fibre for a large manufactory of valuable pina cloth. The fibres should be cleaned on the spot. Fortunately the pineapple planters are not Malays but industrious and thrifty Bugis, most of whom have families. These men could be readily induced to prepare the fibres. Let any merchant offer an adequate price and a steady annual supply will soon be obtained.—*Journ of the Indian Archipelago*, Vol. ii. No. viii. August 1848, page 523.

(2219) PINUS. Cone-bearing pines with long leaves, like the common Scotch fir, are found in Asia, and as far south as the Equator (in Borneo) and also inhabit Arracan, the Malay Peninsula, Sumatra, and South China. It is a very remarkable fact that no Gymnospermous tree inhabits the Peninsula of India; not even the genus *Podocarpus*, which includes most of the tropical Gymnosperms, and is technically coniferous and has glandular woody fibre; though like the yew it bears berries. Two species of this genus are found in the Khasia, and one advances as far west as Nepal. The absence of oaks and of the above genera (*Podocarpus* and *Pinus*) is one of the most characteristic differences between the botany of the east and west shores of the Bay of Bengal. At Churra there is but one pine (*Pinus Khasiana*) besides the yew, (and two *Podocarpi*) and that is only found in the drier regions. Singular to say, it is a species not seen in the Himalaya or elsewhere, but very nearly allied to *Pinus longifolia*, though more closely resembling the Scotch fir than that tree does.—*Hooker Him*: Vol. II. page 282.

(2220) PINUS DEODARA. Devadaroo, or Devdar, is the name the tree is known by amongst the natives where it grows.

A tree of great size, a native of the mountains north of Rohileund. It differs from *P. Larix* in many respects, but most conspicuously in being destitute of the bractes which project beyond the scales of the strobile or cone.

The tree is so exceedingly replete with resin, as to yield a very large proportion of tar. A manufactory of that article was formerly begun, near the skirts of the Almora mountains by Mr. Gott.—*Roxburgh's Flora Indica*. Vol. III. p. 653.

(2221) PINUS EXCELSA.

Kuel, HIND.

(2222) PINUS GERARDIANA.

Chilgoza, HIND.	Rhec, HIND.
Neoza, „	Newr, „
Ganobur, „	

This species occurs in British Garhwal near Bumpa, which appears to be its most Southern habitat. The seeds are edible and are exported

## PHOSPHORESCENCE.

from Cabul and Kunawur, in considerable quantity for sale.

### (2223) PINUS LONGIFOLIA.

Cheer, HIND.		Surul, HIND.
Checl, „		Sulla. „

Of this species there are two varieties in the Himalayas, one with twisted the other with straight fibres, and thus the former is called *Outcha*, its wood being fit only for burning and the latter puka by the natives. The wood of the latter is admirably fitted for building purposes, but if exposed to the action of the weather and water it is quickly destroyed. Lathing made of it is named "dadur."

### (2224) PINUS PINASTER. *Penaster* or *Cluster Pine*.

Kebar, HIND.

### (2225) PINUS PINEA. *Stone Pine*.

### (2226) PINUS ROYLEANA. *Deodar* of *Nepal*.

### (2227) PINUS STROBILUS.

Sundbur, HIND.		Serar, HIND.
<i>Jameson's Saharunpore Report.</i>		

### (2228) PITHECUS, Orang-utang. The following species are known.

(2229) PITHECUS BROOKEI Bl. P. Wurm-bii et F. Abellii, Owen (though neither the species described by Van Wurm, nor that by Dr. Abel, a skull of which is figured in Pl. V. and VI. Mias Rambii, Malay, Brooke. Adult male from Sumatra. A native of Borneo.

(2230) PITHECUS SATYRUS. (L.) apud Brooke, S. Muller, and others: Mias Pappan, Malay, Brooke, Adult female (?) from Borneo.

(2231) PITHECUS MORIO, Owen. Mias Kassar, Malay, Brooke, aged female from Borneo.

(2232) PITHECUS OWENII. Bl. small Orang with short fore-arms. Adolescent female Hab. unknown.—*Ben. As. Soc. Jour. No. 4, page 383.*

(2233) PITHECUS CURTUS, Malay Mias. Chapin.

(2234) PHOSPHORESCENCE, The phenomenon of phosphorescence, says Dr. Hooker, is most conspicuous on stacks of fire-wood. At Darjiling, during the damp, warm, summer months (May to October), at elevations of 5000 to 8000 feet, it may be witnessed every night by penetrating a few yards into the forest—at least it was so in 1848 and 1849; and during my stay there billets of decayed wood were repeatedly sent to me by residents, with inquiries as to the cause of their luminosity. It is no exaggeration to say that one does not need to move from the fireside to see this phenomenon, for if there is a partially decayed log amongst the fire-wood it is almost sure to glow with a pale phosphoric light. A stack of fire-wood, collected near my

## PHYLLANTHUS NIRURI.

host's (Mr. Hodgson) cottage, presented a beautiful spectacle for two months (in July and August), and on passing it at night, I had to quiet my poney, who was always alarmed by it. The phenomenon invariably accompanies decay, and is common on oak, laurel (*Tetranthera*), birch, and probably other timbers, it equally appears on cut wood and on stumps, but is most frequent on branches lying close to the ground in the wet forests. I have reason to believe that it spreads with great rapidity from old surfaces to freshly cut ones. That is a vital phenomenon, and due to the mycelium of a fungus, I do not in the least doubt, for I have observed it occasionally circumscribed by those black lines which are often seen to bound mycelia on dead wood, and to precede a more rapid decay. I have often tried, but always in vain, to coax these mycelia into developing some fungus by placing them in damp rooms, &c. When camping in the mountains, I frequently caused the natives to bring phosphorescent wood into my tent, for the pleasure of watching its soft undulating light, which appears to pale and glow with every motion of the atmosphere; but except in this difference of intensity, it presents no change in appearance night after night. Alcohol, heat, and dryness soon dissipate it; electricity I never tried. It has no odour, and my dog, who had a fine sense of smell, paid no heed when it was laid under his nose.

As far as my observations go, this phenomenon of light is confined to the lower orders of vegetable life, to the fungi alone, and is not dependent on irritability. I have never seen luminous flowers or roots, nor do I know of any authenticated instance of such, which may not be explained by the presence of mycelium or of animal life. In the animal kingdom, luminosity is confined, I believe, to the Invertebrata, and is especially common amongst the Radiata and Mollusca; it is also frequent in the Entomostracous Crustacea, and in various genera of most orders of insects. In all these, even in the sertulariæ, I have invariably observed the light to be increased by irritability in which respect the luminosity of animal life differs from that of vegetable.—*Hooker Him: Jour: Vol. II, pages 150 to 152.*

(2235) PLATINA has been discovered in Ava.

(2236) PHALÆNA. PATROCLUS L. (Cramer, pl. CIX, a, b,) a well known Burmese moth, a splendid species common in collections from China, Assam, Sylhet, and Arakan.

### (2237) PHYLLANTHUS NIRURI, Lin.

Kilanelly, TAM.		Annual Phyllanthus ENG.
Booien Aoonlah, DUK.		Boovooshirum, SANS.
Nela ooshirikch, TEL.		

The white root, bitter leaves, and tender shoots of this plant, are all used in medicine by the Indians, who consider them as deobstruent, diure-

tic and healing, the two first are generally prescribed in powder or decoction, in cases of an over-secreted, acrid bile and in Jaundice, an infusion of the latter together with Vendium seed, is supposed to be a valuable remedy in chronic Dysentery.—*Ains. Mat. Med.* p. 83.

## (2238) POA CYNUROIDES.

Dab, HIND.

Much used in making ropes.

(2239) POLE-CAT, *Black-faced Pole-cat of Tibet.*

Tail one-third of the entire length. Soles clad. Fur long. Above and laterally, sordid fulvous, deeply shaded on the back with black. Below, from throat backwards with the whole limbs and tail, black. Head pale with a dark mask over the face. Snout to vent 14 inches. Head less 3. Tail only 6. Tail with hair, 7. Palma 1½. Planta 2¾.

*Habitat*, the plain of Central Tibet.

A specimen of this interesting animal was obtained in the district of U, on the south of the Sanpú, and was brought along with a specimen of the Tibetan Badger (*Taxidea Leucurus*.) The skin was in good condition, and had the limbs and skull complete. It is seemingly a male, and certainly, a mature animal. The length from snout to vent is 14 inches and the tail is 7 more, so that *Toufæus* only of Tibet, and *Flavigula* of the Himálaya, can compare with it in size.—*Mr. Hodgson in Beng. As. Soc. Journ. No. VI. May 1849.*

(2240) POYLANTHUS TUBEROSA. Cultivated in gardens at Bombay, worn by native women in their hair.—*Graham. (Thomson's Record of General Science Vol. IV. p. 301.)*

(2241) PONGAMIA ATROPURPUREA of *Wallich*, very large tree, abundant in Tenasserim provinces. Flower a beautiful purple.—*Malcom's Travels in South Eastern Asia, Vol. I p. 191.*

(2242) PONG, the Tamil and Malayala name of a tree, *Dalbergia arborea*, which is very heavy and remarkably strong. It grows to about eighteen inches in diameter, and twenty feet in height, and spreads its branches to a great extent. The native carpenters prefer this wood for the knees of vessels, and also for general uses where strength is required. The trunk of the tree is applied to the uses of the block-maker, for shivers, blocks, &c.—*Edye, Mal and Can.*

(2243) POON OR PEON-SPARS. The light-red peon from the forests of Coromandel and Mysore, which can be procured at the port of Mangalore, on the Malabar coast, is considered the best of the growth of India, for the general purposes of lower-masts, top masts, and yards.

The peon-masts, as to strength, compared with

Riga, &c. spars for masts, are superior to any; the weight of those of the proper sort is about the same as Riga fir, and their durability is very great; a set of lower-masts would probably last fourteen or twenty years. During Mr. Edyé's visit supplies of spars could be procured at Mangalore from November to March, but January is the best period. Even then, he said, the transaction should be managed without any previous notice, nor should the number required be made public, but advantage should be taken of the native lists of prices which the merchants will present to the purchaser. If the demand is made public, the market price will advance and combination follow.—*Edye, Mal. and Can.*

## (2244) POPULUS CILIATA.

Chilon, HIND.

Paharee Peepul, HIND.

Ghurb, ,

## (2245) POPULUS PYRIFORMIS.

Sufaida, HIND.

(2246) POREAL PAINI, the Tamil and Malayala name of a wood which may be ranked among the best sort of the Dupi Marams, or Painis, and next to the peons on the coast of Malabar. It might be used for small yards of vessels. At times this wood is called Puni Pains by some of the northern natives, it is of a light-red colour, and grows to about eighteen inches in diameter, and sixty feet long.—*Edye, Mal. & Can.*

(2247) POTOWAR, a town containing remains of Greek sculpture.

## (2248) POTAMOGETON TUBEROSUM.

Suwal, HIND.

This plant is much used in purifying sugar.

(2249) POYANG, an aboriginal race believed by the Malays and Chinese of Malacca, Naning and Rambau, to possess supernatural powers.

(2250) PRINSEP, two brothers, eminent as officers of the Bengal Government and as learned men. H. T. Prinsep as a statesman and numismatist. J. Prinsep as a philologist.

(2251) PSIDIUM POMIFERUM is abundant in some places of Burmah but is not extended over the whole country, and is certainly not indigenous. It grows to the height of twenty or thirty feet, with leaves of pale green, and beautiful large white blossoms. The fruit is about the size of a pear, and a little yellowish when ripe, full of hard seeds, the size of buck-shot. Foreigners generally despise it, as they do many other Indian fruits, which a few experiments would teach them to admire. There are several varieties,—*Malcolm's Travels in South Eastern Asia, V. I. page 180.*

(2252) PTEROSPERMUM ACERIFOLIUM. A useful timber tree affording good shade.

(2253) PUBERTY, amongst Mahomedan

## PUNICA GRANATUM.

girls is called *Baligh-hona* : pyllee sir mylee hona ; also Burron men milna. *Herkl.*

(2254) PUDDIEM. The Puddiem or Payah, a Nepaul tree, resembles, in its leaf and wood, the English cherry, the wood being held in sanctity by the natives.—*Smith's Nepaul.*

(2255) PULLIA MARUM, known to Europeans by the name of "tamarind." There are two sorts of the tamarind wood, the light and the dark. These trees grow to about seven or eight feet in diameter at the butt, while that of the body of the tree is about five feet. This part is seldom more than ten feet long, when it branches out into curves of various dimensions. It is considered valuable, from the quantity of fruit it produces, which is used medicinally. The acid is used in cookery. These trees are cultivated in gardens, and spread their branches to a great extent. The timber is remarkably heavy and hard, much like lignum vitæ; and is used generally for sheeves in blocks, and such purposes.—*Edye M. sc.*

(2256) PULO CHIKUKOH. A little island near Singapore.

(2257) PULO TIMMUKUL. A little island adjoining Singapore, 60 yards in diameter and feet high.

(2258) PUNA BALLE in Tamil, and Punga Marum in Malayala (*Pongamia glabra*). This is a beautiful tree and of much value; it grows to about two and a half feet in diameter, and from ten to fifteen long, spreading its branches to a great extent, and into curves of various dimensions, which are valuable for native uses, particularly in building country vessels. It produces a fruit from which oil is extracted, and used for lamps, &c. The Arabs prefer this oil to any other to mix with chunam, for the purpose of covering the bottoms of their vessels to preserve them from worms; it is also used for the purpose of curing rheumatic pains, by being applied warm with friction.—*Edye, M. and C.*

(2259) PUNICA GRANATUM. The Pomegranate is cultivated to a very small extent in gardens by both Burmese and Europeans. (*Mason.*) The roots are hard, heavy, woody, knotty, covered with a bark yellowish grey externally, internally yellow, inodorous, astringent, devoid of bitterness, very rich in tannic acid to which they owe their established vermifuge properties. The ancients used these roots for the expulsion of tape-worm, but the practice had fallen into neglect when it was revived by Buchanan and others. The bark of the root is given in a decoction of 2 ounces in 2 lbs. of water, reduced by evaporation to 12 ounces. This quantity is divided into 6 doses to be taken daily, and repeated for four or five days.

The flowers (*balanistum*) are rich in tannic and

## PUTTOOAS.

gallic acid, and are used in dyeing, and in medicine as astringents; with alum they make a beautiful red ink.—*O' Sh. p. 338.*

(2260) PUN-JAY-REE, Hind. A caudle given to lying-in-women.—*Herkl.*

(2261) PUOAM, the Tamil name of a tree of a light-red colour (*Schlechteria*) much like the Spanish mahogany. It is generally curved in its growth, and is considered very durable. It grows to about twenty-four inches in diameter, and seldom more than twenty feet high. It produces a fruit which the natives pickle, and from which also they extract an oil, which they use for rheumatic gout, bruises, and various complaints: it is considered by them to be valuable. The weight of this wood is about thirty-seven and a half pounds the cubic foot.—*Edye M. & C.*

(2262) PUOAM PARASOM, the Tamil name of a tree (*Butea*) with which the natives of Malabar are well acquainted, and which they use for the masts and yards of pattamahs. It grows to about sixty feet high, and fifteen inches in diameter: it may be considered inferior to the mast peon before described.—*Edye M. and C.*

(2263) PURITY, Mahomedans follow the Jews in their attention to outward purity. Before praying, it is necessary that one be undefiled. There are degrees of defilement, the least of which requires that the hands, arms and feet be washed before praying and for this purpose Mosques are always provided with cisterns or tanks of water: in the desert sand is used. After greater impurities it is necessary that the whole body be washed, hence the longer they remain undefiled the purer their life; Wuzzu, expresses the ablution and Hedas, the state of defilement, during the continuance of which they cannot pray. The Mulana Abu Ashah was said to use the water of purification twice in a month—that is, his life was so pure that for a whole fortnight he was not so much defiled as to make necessary a total ablution. *Vir præcipue emissionem seminis fœdat at mulier menstruorum.*—*Journ. Ind. Arch. Vol. V. No. 11.*

(2264) PUSHTOO. V. AFFGHAN.

(2265) PUTRANJIVA ROXBURGHII.

Jeapota,	Jootce,
Putrajiva.	

Nuts strung round the necks of children to keep them in health. Extensively sold in the bazars of upper India.

(2266) PATTEE, Hind. a Mahomedan rite held the third day after a woman's confinement.—*Herkl.*

(2267) PUTTOOAS OR JUANGA, a forest tribe inhabiting the tributary Mahals of Cuttack to the South of Singbhoom, in the Mehals or Killahts of Keonjur, Pal Leyra, Dheknaht, and

## QUERCUS.

Hindole. They are said to number 1,500 persons of all ages and to occupy 15 different localities, thirty villages in Keonjur, and six or seven in Pal Leyra and Hindole. Their stature is diminutive, men 5 ft. 2 in. women, 4 ft. 3 in. or 4 in. The men dress like the peasantry of the country: the women however only cover their

## QUERCUS SEMICARPIFOLIA.

persons in front and behind by a bunch of twigs with the leaves attached, kept up by a strip of bark or a string of beads. These leaves are changed daily. Their pursuits are chiefly those of the chase, in which they employ dogs, and the bow and arrow.—*Ben. As. Journ. No. 4 of 1856.*

## Q.

(2268) QUAH-LAY, Malay. (*Mucuna pruriens.*)

(2269) QUERCUS, OAK.

Baalut, ARAB.	Quercus. LAT.
Eeg, DAN.	Dab, POL.
Eik, DUT.	Roble Carbahlo, PORT.
Chene, FR.	Dub, RUS.
Eiche, GER.	Roble, SP.
Quercia, IT.	Ek, SW.

A genus of well-known timber trees (*Quercus*), embracing about 150 species. Several species are indigenous in the Tenasserim provinces.—Wallich found seven different species of oak *Quercus fenestrata*, *turbinata*, *velutina*, *Amherstianus*, *Tirbbæ*, growing in Burmah and on the Tenasserim Coast, and all afford useful timber, though inferior to the English oak. No oak nor chestnut ascends above 9000 feet in the interior of Sikkim, where they are replaced by a species of hazel (*Corylus*); in the North Himalaya, on the other hand, an oak (*Quercus semecarpifolia*, see vol. i. p. 187) is amongst the most alpine trees, and the nut is a different species, more resembling the European. On the outer Sikkim ranges, oaks (*Q. annulata*?) ascend to 10,000 feet, and there is no hazel. It is not generally known that oaks are often very tropical plants; not only abounding at low elevations in the mountains but descending in abundance to the level of the sea. Though unknown in Ceylon, the Peninsula of India, tropical Africa, or South America, they abound in the hot valleys of the Eastern Himalaya, East Bengal, Malay Peninsula, and Indian islands; where perhaps more species grow than in any other part of the world. Such facts as this disturb our preconceived notions of the geographical distribution of the most familiar tribes of plants, and throw great doubt on the conclusions which fossil plants are supposed to indicate.—*Hooker, Him. Jour. Vol. II. p. 140 & 336. Foulkner, Mason.*

Of this genus, Mr Jameson gives the following species as in the Saharanpore gardens.

(2270) QUERCUS MUTABILIS.

(2271) QUERCUS DILATATA, HIND. Mohro, Kilong and Tilong,

(2272) QUERCUS ACUMINATA, HIND. Hunne,

(2273) QUERCUS NITIDA,

(2274) QUERCUS CORIACEA,

(2275) QUERCUS ANNULATA, HIND. Hunne. Phuliat, and Funiat.

(2276) QUERCUS. The following are other Indian species of this genus.

(2277) QUERCUS INCANA, Himalayan Oak.

Ban also Bang, HIND.

Its acorns are sold in the Bazaars of the N. W. Provinces under the name of Shah Baloot.

(2278) QUERCUS ACUMINATA.

Hunnee, HIND.

(2279) QUERCUS ANNULATA.

(2280) QUERCUS CORIACEA.

(2281) QUERCUS DILATATA.

Mohroo; also Kilong also Tilong, HIND.

(2282) QUERCUS, GUNGOOTRIENSIS.

(2283) QUERCUS, LANATA VELLANUGINOSA.

Reang, HIND.

In many localities in Kumaon this species takes the place and name of *Quercus incana*.

(2284) QUERCUS MUTABILIS.

(2285) QUERCUS NITIDA.

(2286) QUERCUS SEMICARPIFOLIA.

Kursoo, HIND.

Its acorns are named Shah Baloot.

## R.

(2287) RAYAT LAUT, a sailor race of the Indian Archipelago, adventurous navigators.

(2288) RANDEA DUMETORUM, *Rubiaceae* Icon. 580.

Madoocarray marum, TAM.

This seldom exceeds the size of a large shrub and therefore scarcely merits notice here, the wood is hard and close grained. The fruit is used in Malabar to poison fish.

(2289) RATANS, GROUND. The excellent walking sticks known to the English under this name, are made from the *Rhapis flabelliformis* which grows in Lin kin and Southern China.

(2290) RAIN. As the occasional showers which fall throughout the year in England, are unknown in most Asiatic countries, the first particular to attend to in examining their climate, is the season and the quantity of the periodical rains. It is this which regulates husbandry, and on which in many countries the temperature and succession of the seasons in a great measure depend.

The most remarkable rainy season, is that called in India the south-west monsoon. It extends from Africa to the Malay peninsula, and deluges all the intermediate countries within certain lines of latitude, for four months in the year. In the south of India this monsoon commences about the beginning of June, but it gets later as we advance towards the north. Its approach is announced by vast masses of clouds that rise from the Indian Ocean, and advance towards the north east gathering and thickening as they approach the land. After some threatening days, the sky assumes a troubled appearance in the evenings, and the monsoon in general sets in during the night. It is attended with such a thunder-storm as can scarcely be imagined by those who have only seen that phenomenon in a temperate climate. It generally begins with violent blasts of wind, which are succeeded by floods of rain. For some hours lightning is seen almost without intermission, sometimes it only illuminates the sky, and shows the clouds, near the horizon; at others it discovers the distant hills, and again leaves all in darkness, when in an instant it re-appears in vivid and successive flashes, and exhibits the nearest object in all the brightness of day. During all this time the distant thunder never ceases to roll, and is only silenced by some nearer peal, which bursts on the ear with such a sudden and tremendous crash as can scarcely fail to strike the most insensible heart with awe. At length the thunder ceases, and nothing is heard but the continued pouring of the rain, and the rushing of the rising streams. The next day presents a gloomy spectacle: the

rain still descends in torrents, and scarcely allows a view of the blackened fields: the rivers are swollen and discoloured, and sweep down along with them the hedges, the huts, and the remains of the cultivation which was carried on, during the dry season, in their beds.

To persons who have long resided in India, these storms lose much of their grandeur, yet they sometimes rise to such a pitch, as to make an impression on those most habituated to them. I have been told by a gentleman who had been for sometime in Malabar, the province most distinguished for the violence of the monsoon, that he there heard a clap of thunder which produced a silence of a minute in a large party of officers, and made a great part of the company turn pale.

This lasts for some days, after which the sky clears, and discovers the face of nature changed as if by enchantment. Before the storm, the fields were parched up, and except in the bends of the rivers, scarce a blade of vegetation was to be seen: the clearness of the sky was not interrupted by a single cloud, but the atmosphere was loaded with dust, which was sufficient to render distant objects dim as in a mist and to make the sun appear dull and discoloured, till he attained a considerable elevation: a parching wind blew like a blast from a furnace, and heated wood, iron and every other solid material, even in the shade; and immediately before the monsoon, this wind had been succeeded by still more sultry calms. But when the first violence of the storm is over, the whole earth is covered with a sudden but luxuriant verdure: the rivers are full and tranquil: the air is pure and delicious; and the sky is varied and embellished with clouds. The effect of the change is visible on all the animal creation, and can only be imagined in Europe by supposing the depth of a dreary winter to start at once, into all the freshness and brilliancy of spring. From this time the rain falls at intervals for about a month, when it comes on again with great violence, and in July the rains are at their height: during the third month, they rather diminish, but are still heavy: and in September they gradually abate, and are often entirely suspended, till near the end of the month, when they depart amidst thunders and tempests as they came. Such is the monsoon in the greater part of India. It is not, however, without some diversity, the principal feature of which is the delay in its commencement, and the diminution in the quantity of rain, as it recedes from the sea. In the countries which are the subject of the present inquiry, the monsoon is felt with much less violence than in India, and is exhausted at no great distance from the sea, so that no trace of it can be perceived at Candahar.

A remarkable exception to this rule, is, however, to be observed in the north-east of Afghanistan, which although much further from the sea than Candahar, is subject to the monsoon, and what is equally extraordinary, receives it from the east.

These anomalies may perhaps be accounted for by the following considerations. It is to be observed that the clouds are formed by the vapour of the India ocean, and are driven over the land by a wind from the southwest. The causes of the southwest wind require a separate discussion, unconnected with my object, which is to explain the summer rains of the kingdom of Cabul. It is sufficient for my purpose that the prevalence of this wind to the extent alleged, is universally acknowledged. Most part of the tract in which the Kingdom of Cabul lies, is to leeward of Africa and Arabia, and receives only the vapours of the narrow sea between its southern shores and the latter country, which are but of small extent, and are exhausted in the immediate neighbourhood of the coast. India lying further east, and beyond the shelter of Africa, the monsoon spreads over it without any obstruction. It is naturally most severe near the sea from which it draws its supplies, and is exhausted after it has past over a great extent of land. For this reason, the rains are more or less plentiful in each country, according to its distance from the sea, except in those near high mountains, which arrest the clouds, and procure a larger supply of rain for the neighbouring tracts, than would have fallen to their share, if the passage of the clouds had been unobstructed.

The obstacle presented to the clouds and winds by the mountains has another effect of no small importance. The southwest monsoon blows over the ocean in its natural direction; and, though it may experience some diversities after it reaches the land, its general course over India may still be said to be towards the north east, till it is exhausted on the western and central parts of the peninsula. The provinces in the northeast receive the monsoon in a different manner: the wind which brings the rains to that part of the continent, originally blows from the south west, over the Bay of Bengal, till the mountains of Hemalleh, and those which join them from the south, stop its progress, and compel it to follow their course towards the north west. The prevailing wind, therefore, in the region southwest of Hemalleh, is from the south east, and it is from that quarter that our provinces in Bengal receive their rains. But when the wind has reached so far to the north west as to meet with Hindoo Coosh, it is again opposed by that mountain, and turned off along its face towards the west till it meets the projection of Hindoo Coosh and the range of Solimaun, which prevent its further progress in that direction, or at least compel it to part with the clouds with which it was loaded. The effect of

the mountains in stopping the clouds borne by this wind, is different in different places. Near the sea, where the clouds are still in a deep mass, part is discharged on the hills and the country beneath them, and part passes up to the north west; but part makes its way over the first hills, and produces the rains in Tibet. In the latitude of Cashmeer, where the hills are considerably exhausted, this last division is little perceived: the southern face of the hills and the country still farther south is watered; and a part of the clouds continue their progress to Afghanistan; but few make their way over the mountains, or reach the valley of Cashmeer. The clouds which pass on to Afghanistan are exhausted as they go, the rains become weaker and weaker, and at last are merely sufficient to water the mountains, without much affecting the plains at their base.

The above observations will explain, or at least connect the following facts. The south-west monsoon commences on the Malabar coast in May, and is there very violent, it is later and more moderate in Mysore; and the Coromandel Coast covered by the mountainous countries on its west, is entirely exempt from it or only felt in the form of occasional showers. Further north, the monsoon begins early in June, and loses a good deal of its violence, except in the places influenced by the neighbourhood of the mountains or the sea, where the fall of water is very considerable. About Delhi it does not begin till the end of June, and the fall of rain is greatly inferior to what is felt at Calcutta or Bombay. In the north of the Punjaub, near the hills, it exceeds that of Delhi; but, in the south of the Punjaub, distant both from the sea and the hills, very little rain falls.

The countries under the hills of Cashmeer, and those under Hindoo Coosh, (Pukhlee, Boonere, and Swaut) have all their share of the rains; but they diminish as we go west, and at Swaut are reduced to a month of clouds, with occasional showers. In the same month (the end of July and beginning of August) the monsoon appears in some clouds and showers at Peshawur, and in the Bungush and Khuttuk countries. It is still less felt in the valley of the Cabul river, where it does not extend beyond Lughmann; but in Bajour and Punjora, under the southern projection, in the part of the Caufir country, which is situated on the top of the same projection, and in Teera, situated in the angle formed by Tukht-i-Solimaun and its eastern branches, the south west monsoon is heavy, and forms the principal rains of the year. There is rain in this season in the country of the Jaujees and Torees, which probably is brought from the north by the eddy in the winds, but I have not information enough to enable me to conjecture whether that which falls in Bunnoo and the neighbouring countries is to be ascribed to this cause or to the regular monsoon from the south west — *Elphinstone's Kingdom of Cabul*, page 126.

In the hot season, Madras is often visited with refreshing non-monsoon rains which much reduce the heat of that period, and produce forage for cattle. In 1854, Major Worster published a table of monthly and yearly results of the Observations of the Rain Gauge, at the Madras Observatory, from 1813, to 1854, showing an average annual fall of  $49\frac{1}{2}$  inches of rain during the forty two years. Of this amount,  $29\frac{1}{2}$  inches fell during the monsoon months of October, November and December, the other 20 inches falling during the other nine non-monsoon

months of the year. On looking over Major Worster's table we observe a striking connexion between the amount falling in the non monsoon months with the fall in the October, November and December following; and these falls seem to augur a copious monsoon for the monsoon year. In the 42 years of the table, there were 20 years, in which the fall in the non-monsoon months was above and 22 years in which it was under the average, and the result of an examination, may thus be briefly stated. In the 20 years when the rains of the non-monsoon

months have been at or above the average of 20 inches, the rains of the following monsoon months have likewise, in 16 years, been at or above the average of 29½ inches : and in the 22 years when the rains of the non-monsoon months have been below their average, in 15 instances, the next monsoon has been deficient.

(2291) RAMJUNNEE, a Mahomedan dancing girl.

(2292) RAMSANEHI OR FRIENDS OF GOD, A sect of Hindu schismatics in Western India.

(2293) RAJ-MALA OR CHRONICLES OF TRIPURA. A Bengali poem.

REPTILES, *inhabiting the Malayan Peninsula and islands collected or observed by THEODORE CANTOR, Esq., M.D., Bengal Medical Service.* From the Journal of the Asiatic Society, Nos. 181 and 183 for July and October, 1847.

*Note.* [Localities printed in Italics signify those from whence the animals of the Catalogue were obtained ; in ordinary type those previously given by authors. The descriptions are in most cases taken from life ; in the few in which it is expressly noted, shortly after death ; in none from specimens preserved in spirits of wine.]

## CHELONIA.

FAM. ELODIDÆ, or MARSH-TORTOISES, *Dum. and Bibr.*

SUB-FAM. CRYPTODERINÆ, *Dum. and Bibr.*

(2294) *Gen. GEOEMYDA*, Gray.

Head covered with thin continued skin ; chin not bearded. Legs strong, not fringed behind. Toes 5-4, strong, short, free, covered above by a series of shields ; claws short. Tail tapering ; shell depressed, three-keeled ; hinder edge strongly toothed. Sternum solid, broad truncated before, notched behind ; gular plate linear, band-like, small ; axillary and inguinal plates small.

(2295) *GEOEMYDA SPINOSA* (Bell.)

*Emys spinosa*, Bell apud Dum. and Bibr.

*Emys bispinosa*, Schlegel.

*Testudo emys*, Müller?

*Geoemyda spinosa*, Gray.

Shell oblong, subquadrate, keeled, flattened above, chestnut coloured, front and hinder edge strongly serrated ; vertebral plates broad, first subercoolate ; costal plates with a posterior, sub-superior areola, with a slight subconic tubercle ; beneath yellow, brown rayed ; *young* depressed, pale brown, bluntly keeled, with a distinct spine in the areola of each discal plate.

*Habit.*—*Pinang Hills*. Sumatra.

Two individuals were observed by the Hon'ble Sir William Norris, late Recorder of H. M. Court of Judicature in the Straits of Malacca, on the

Great Hill at Pinang, at a distance from water. The colour of the shell is a dirty brownish ochre, here and there with sooty rays, which numerous-ly intersect the concave sternum. The keel, the marginal spines, and the costal tubercles are nearly obliterated, and the shell presents frequent marks of corrosion. The larger individual is of the following dimensions :—

Length of the head,..... 1 <sup>5</sup>/<sub>8</sub> Inch.

Do. do. neck,..... 1 <sup>5</sup>/<sub>8</sub>

Do. do. shell,..... 8

Do. do. tail,..... 1 <sup>5</sup>/<sub>8</sub>

A large tick was firmly adhering to the throat of one of these tortoises, the presence of which however does not indicate an exclusively terres-trial life, as one species at least of the *Ricinæ* (*Ixodes ophiophilus* Müller ?) occurs on aquatic as well as terrestrial serpents. The following are the characters of *Ixodes geoemydæ*. The short sucker is depressed, slightly widening towards the bifid apex, and encased by the palpi. Above, and at a short distance from the latter, are two minute rounded fossæ. The cephalic, tetrago-nal plate is of a reddish brown colour, with a yellow spot at the posterior angle. The oval body is dark pearl-coloured. On each side close to the articulation of the posterior leg appears a small rounded horny plate. The legs are red-dish brown with a yellow spot at each of the joints, except the last. Swollen, as the tick ap-peared, it measured six-eighths of an inch in length ; half an inch in breadth.

(2296) *Gen. EMYS*, Brogniart.

Head moderate, covered with a thin hard skin ; chin not bearded. Feet short, covered with scales ; toes 5-4, strong, shielded above, webbed to the claws. Tail moderate. Shell depressed. Sternum solid, broad, truncated before, notched behind, affixed to the thorax by a bony symphysis, covered by the ends of the pectoral and abdominal plates ; axillary and inguinal plates moderate, distinct.

A.—*Vertebral plates lozenge-shaped.*—Gray.

(2297) *EMYS CRASSICOLLIS* Bell, MSS. apud Gray.

*Emys crassicollis*, Bell, apud Dum. and Bibr.

*Emys spengleri*, Var, Schlegel.

Shell ovate, oblong, rather convex, revolute on the sides and deeply toothed behind, black, slight-ly three-keeled ; keels close ; first vertebral plate elongate, six-sided ; sternum flat, pale, and keeled on the sides ; head and neck thick, black.

*Habit.*—*Malayan Peninsula*, (*Pinang*), Suma-tra, Java.

In Malayan individuals, numerously inhabiting rivulets and ponds in the valleys, the throat is whitish, and a small white spot appears on each side of the occiput. The vertebral keels and the lateral spines become obliterated with age. The

# MALAYAN PENINSULA AND ISLANDS.

largest individual observed was of the following dimensions:—

Length of the head,.....	1 $\frac{5}{8}$ Inch.
Do. do. neck,.....	1 $\frac{5}{8}$
Do. do. shell,.....	9
Do. do. tail,.....	1 $\frac{1}{2}$

It feeds upon frogs and also upon shell-fish and animal offal. Old Malay women, who may be seen after every heavy fall of rain, spending hours, rod in hand, over the overflowing ditches, out of which their huts rise, are often ludicrously disappointed on perceiving this tortoise on the hook.

B. *Vertebral plates broad, six-sided.* Gray.—

(2298) *EMYS PLATYNOTA*, Gray.

“Katong” of the Malays of the Peninsula.

Shell ovate, convex, yellow dotted, with the centre of the back quite flat, as if truncated; shields striated, nucleus central; vertebral shields broader than long, six-sided, 5th keeled; the front and hinder margin strongly toothed; sternum flat, truncated before; and slightly notched behind; tail moderate, tapering.

*Habit.*—*Malayan Peninsula, Pinang, Sumatra.*

Mr. Gray's description refers to the young animal, of which the length of the shell is given in *Proceed. Zoolog. Soc.* 1834. p. 54 as 9 inches. The representation of *Emys platynota* in *Illust. Ind. Zool.* from its size, and the strongly toothed flat front and hind margins of the shell, also appears to be a young animal. The penultimate, the fourth, vertebral shield is represented as divided in two pieces, which if so in the original, must be accidental, as normally the fourth vertebral shield is six-sided, and in size nearly equalling the preceding. The nuclei of the costal shields are more central than represented in the plate.

In the living adult animal the head, neck, shell, tail and feet are of a dirty yellowish or greenish brown, which becomes paler on the sternum. The nuclei of the vertebral shields are slightly raised. The costal shields are depressed, their sides sloping towards the nuclei, thus forming as it were very shallow hexagonal basins. The front and hind margins are broadly revolute, their toothed appearance worn off. The sternum is slightly concave in the centre. The largest individual was of the following dimensions:

	Feet.	Inch.
Length of the head,.....	0	3
Do. do. neck,.....	0	3
Do. do. shell,.....	1	7 $\frac{1}{2}$
Do. do. tail,.....	0	2 $\frac{1}{2}$

It lived in my garden at Pinang upwards of a twelvemonth, apparently without food, and it was never observed to enter a tank. The shell bears deep white marks of corrosion, in appearance like that observed in Testacea inhabiting stagnant water. The animal suffered itself to be touched with impunity, never offering to scratch

or bite. This tortoise inhabits the valleys, but is apparently not numerous.

(2299) *EMYS TRIVITTATA*, Dumeril and Bibron.

Shell smooth, entire, subcordiform, arched, yellowish green, and with three broad longitudinal black bands; jaws toothed.

*Habit.*—*Malayan Peninsula, Pinang, Bengal.*

It inhabits rivers and ponds on the Malayan Peninsula, but appears not to be numerous. In the Malayan adult animal there is a large black spot situated at the anterior, lower angle of the marginal shields, there is no trace of a keel in the centre of the vertebral shields, and the very minute nuchal shield is triangular, with the apex towards the vertebral shields. The shield is rather oval than subcordiform. The sternum is slightly arched, of a pale whitish yellow. The largest individual was of the following dimensions:

	Feet.	Inch.
Length of the head,.....	0	3
Do. do. neck,.....	0	2 $\frac{1}{2}$
Do. do. shell,.....	1	6
Do. do. tail,.....	0	2 $\frac{3}{8}$

(2300) *Gen. CISTUDO*. Fleming.

Head moderate, covered with a thin hard continued skin, Toes 5-4 webbed to the claws, web thick, with a small intermediate lobe between the claws. Tail short. Shell convex, ovate, or hemispherical. Sternum broad, rounded before and behind, completely closing the cavity of the thorax, affixed to it by a ligamentous symphysis, and divided by a cross suture between the pectoral and abdominal plates. Sternal shields twelve. Inguinal and axillary plates very small, but distinct. Marginal plates 23-27. Nuchal plate small or wanting.

(2301) *CISTUDO AMBOINENSIS*, (Daudin).

SYN.—*Testudo amboinensis*, Daudin.

*Emys amboinensis*, and *couro*, Schweigger.

*Tortue à boîte d'Amboine*, Bosc.

*Terrapene amboinensis*, Merrem.

*Kinosternon amboinense*, Bell.

*Cistuda amboinensis*, Gray.

*Terrapene couro*, Fitzinger.

*Emys Couro*, apud Wagler.

*Terrapene bicolor*, Bell.

*Emys Couro*, Var. Schlegel, apud Gray.

“Baning” of the Malays of the Peninsula.

*Habit*—*Malayan Peninsula, Singapore. Java, Amboina, Philippine Islands, Tenasserim provinces.*

Shell hemispherical, slightly three-keeled, blackish, margin broad expanded, nuchal shield linear; sternum black and yellow-varied; animal blackish, varied with yellow, head dark with two broad yellow streaks on each side.

The dorsal keels become obsolete with age, and the margin of the shell, particularly the posterior part, becomes revolute. This species appears to be numerous in the valleys, in ponds,

rivulets and paddy fields. It is very timid, withdrawing its head and limbs when handled, though it neither bites nor scratches. The largest individual observed was of the following dimensions :

Length of the head, .....	2 inch.
Do. do. neck, .....	2 $\frac{1}{8}$
Do. do. shell, .....	7
Do. do. tail, .....	1

*Gen. TETRAONYX. Lesson.*

Toes five ; nails 4-4 ; sternum solid, broad with six pairs of shields ; 25 marginal shields.

(2302) *TETRAONYX AFFINIS, N. S.*

*Young.*—Shell orbicular, its breadth exceeding its length ; the back sharply keeled longitudinally, slightly arched, laterally depressed ; costal shields with a tubercular nucleus at the posterior margin ; greyish green olive, minutely spotted with brown ; edge sharply toothed, pale greenish yellow. Sternum, truncated in front, angularly indented behind, narrow, yellow ; laterally keeled, compressed, pale yellowish green.

*Habit.*—Sea off Penang.

The outline of the shell and its composing shields strikingly resemble the young of *Cyclemys orbiculata*, Bell, \*

\* Note. *Emys dentata* Illust. Ind. Zoolog.—*Emys dhor*, Gray.—*Emys hasseltii*, Boie.—*Emys spengleri*, Var. Schlegel.—*Cistudo diardii*, Dum, and Bibr.

The nuchal shield (wanting in one individual,) is small, subrectangular or subtriangular, with the base directed backwards. The vertebral shields are strongly keeled, laterally sloping, hexagonal, broader than long, which however, with the first is less the case than with the rest ; the second, third and fourth are the broadest, and of nearly equal size ; the fifth assumes a broadly truncated triangular shape. The costal shields are nearly all as broad as long ; the first, second and third have each a tubercular nucleus in the centre of the posterior margin, the fourth is smooth, and a little smaller than the preceding. The first pair of marginal shields is truncated triangular, the second, and third subrectangular ; the fourth, sixth, and eighth pentagonal ; the rest subrectangular. In all, the posterior external angle forms a more or less sharp spine, directed over the anterior external margin of the next shield. From the first to the sixth the shields gradually increase in size, the sixth being the largest and broadest, from which the following gradually decrease towards the twelfth pair, and their angular spines become obsolete. The sternum consists of two parts : one central, and two lateral, formed by the sterno-costal processes of the two central pairs, sharply sloping towards the marginal shields. The central part is longitudinally a little concave, narrowing towards both extremities, truncated in front, angularly indented behind. The gular pair of shields is very

short, broadly subtriangular with the posterior margin concave, curved backwards. The second, and fifth pairs are of nearly equal size, subquadriangular, their external margins forming a sharp ridge. The central part of the third and fourth pairs is subrectangular, broader than long, their margins forming a sharp ridge where they join the sterno costal processes. The latter are of nearly equal size, longer than broad, their united length being less than one half of the central part of the sternum. The sixth pair is subrhomboidal, longer than broad. The axillary and inguinal pairs are large ; the former subrhomboidal or lozenge-shaped, the latter subtriangular. The head is conic ; the muzzle short pointed ; the vertex irregularly wrinkled. On the temples, cheeks, and round the orbits, and the lower jaw appear some large polygonal scales. The occiput, angle of the mouth, and the rounded tympanum are covered with similar minute scales. The eyes are large, prominent ; the iris silvery grey ; the pupil round black. The nostrils are minute, round, horizontally pierced, close together at the apex of the muzzle. The jaws are minutely toothed ; the upper has at the symphysis two larger teeth, between which fits a similar single one in the lower jaw, thus hermetically closing the mouth. The neck, the throat and the other soft parts are studded with minute tubercles, except the fore-arm, the posterior tarsal margin, and the back of the fingers and toes, which are covered with broad, but very short, polygonal scales. On the ulnar margin of the fore-arm are four to five large rounded flexible scales. The interdigital web is large and lax. The nails are strong, of nearly equal size, sharp, and arched. The conical tail reaches but little beyond the shell, with a longitudinal furrow behind the vent. The head, neck, throat and the limbs are of the same greyish green olive as the shell. The interdigital membrane is blackish, except the web connecting the fourth and fifth (nailless) toe, which is of a bright greenish yellow colour. Of three individuals observed, differing but little in size, the largest was of the following dimensions :

Length of the head, .....	0 $\frac{6}{8}$ inch.
Do. do. neck, .....	0 $\frac{3}{8}$
Do. do. shell, .....	2 $\frac{4}{8}$
Do. do. tails, .....	0 $\frac{4}{8}$

Greatest transverse diameter of the shell, 2  $\frac{1}{8}$ .

Two were at different times found in fishing stakes placed along the sea-shore of Pinang ; a third was also taken out of the sea with a small hook, baited with a shrimp. The Malays assert that this tortoise also inhabits estuaries and rivers on the Peninsula, and that it grows to a considerable size. The young is very timid, withdrawing the head and extremities when touched, and thus it remained immoveable while a sketch was taken.

From the description of the young of *Tetraonyx lessonii*, Dum. and Bibr. given in *Erpetologie*

# MALAYAN PENINSULA AND ISLANDS.

*Generate*, tome 2, p. 338, and from the plates of *Emys batagur* and *Emys baska*, in *Illust. Ind. Zool.*, from B. Hamilton's MSS., the present appears to differ in too many particulars, to warrant the conclusion of its being the young of those of that species.\*

\* Note. M.M. Dumèril and Bibron describe them as two distinct species; Mr. Gray is of opinion that they are identical.

The detailed description of the young will enable future observers who may succeed in examining the adult, finally to decide the question.

FAM: POTAMIDA, OR RIVER-TORTOISES, *Dum and Bibr.*

(2303) *Gen. GYMNOPUS*, Dum. and Bibr.

(*Trionyx*, Geoffroy.—*Aspidonectes*, Wagler.—*Tyrse*, *Dogania*, *Chitra*, Gray.)

Shell cartilaginous in its circumference, very broad, flexible behind, and externally not bony; sternum too narrow behind completely to cover the extremities, when the animal withdraws them under the shell,

(2304) *GYMNOPUS CANGETICUS*, (Cuvier).

SYN.—*Testudo ocellatus*, (Young) } Buchan.

*Testudo hurum*, } Ham.

*Testudo chim*, (Adult) } MSS.

*Trionyx gangeticus* Cuvier.

*Trionyx hurum*, Gray.

*Trionyx hurum*, *Illust. Ind. Zool.*

*Trionyx ocellatus*, *Illust. Ind. Zool.* (Young.)

*Trionyx gangeticus*, Var, Guerin. (Young.)

*Gymnopus ocellatus*, Dum. and Bibr. (Young.)

*Gymnopus devaucellii*, Dum. and Bibr.

*Tyrse gangetica*, Gray: Catal.

*Young*.—(*Testudo ocellatus*, B. Ham. MSS).

Head above pale olive with one large yellow spot between the eyes and a similar behind each eye; neck, limbs and posterior margin of the shell dark olive with paler round spots; shell olive with black irregular lines, and 4 or 5 central ocelli, black in the centre, edged with red, round with a black ring; sternum pale whitish-olive.

*Testudo hurum*. B. Ham, MSS. is the transition state of the former, being about changing the livery. Head yellow olive, with irregular dark lines; shell light olive, vermiculated with blackish or dark olive. The four ocelli are present, but are altered in colours and shape: the centre, instead of being black, is like the rest of the surface, light olive, vermiculated with black; the red ring is changed to black, and the outer black one to light olive. The shape is changed from round to irregular oval.

(*Adult. Testudo chim*, B. Ham. MSS.) Dark olive-green, *vermiculated*, and spotted with light olive brown. Beneath greenish white.

*Habit*.—*Malayan peninsula*, *Pinang* (Rivers and Sea-coast.) Rivers and Bay of Bengal.

It is of fierce habits, desperately defending itself by biting, emitting when excited a low, hoarse, cackling sound. At Pinang the present

species appears to be far less numerous than the two following. The largest individual was of the following dimensions:

	Feet	Inch.
Length of the head,...	0	4
Do. do neck,...	0	4 $\frac{1}{8}$
Do. do shell,...	1	11
Do. do tail,...	0	5

(2305) *GYMNOPUS CARTILAGINEA*, (Boddaert).

SYN.—*Young*.

*Testudo cartilaginea*, Boddaert.

*Testudo boddaertii*, Schneider.

*Testudo rostrata*, Thunberg?

*Testudo rostrata*, apud Schoepff, and Daudin.

*Trionyx stellatus*, Geoffroy.

*Trionyx stellatus*, apud Merrem.

*Aspidonectes javanicus*, Wagler. *Adult*.

*Trionyx javanicus*, Geoffroy.

*Trionyx javanicus*, apud Schweigger and Gray.

*Gymnopus javanicus*, Dumeril and Bibron.

*Tyrse javanica*, Gray: Catal.

*Very Young*.—Above olive green; the head and upper part of the neck with numerous small white spots, becoming larger and more distant on the cheeks and chin; on the vertex, two round black spots; on the occiput two diverging black lines; the shell with several large black white-ringed spots, between which numerous smaller indistinct white spots; margin pale white; several longitudinal ridges, composed of close minute tubercles. Beneath greenish white.

*Older*.—Above uniformly olive-green; the longitudinal ridges of the shell consisting of tubercles, more distant and proportionally smaller than in the very young.

*Habit*.—*Malayan Peninsula*, *Pinang*. Java, Dikhun, "India," "China."

This species is numerous in rivers and ponds. The largest individual observed was of the following dimensions:

Length of the head,.....	2 $\frac{1}{8}$ Inch.
Do. do neck,.....	2 $\frac{3}{8}$
Do. do shell,.....	6 $\frac{3}{8}$
Do. do tail,.....	0 $\frac{6}{8}$

(2306) *GYMNOPUS, INDICUS*, (Gray)

SYN.—*Testudo chitra*, Buchan. Ham. MSS.

*Trionyx indicus*, Gray.

*Trionyx aegyptiacus*, Var. *indica*, Gray.

.*Ill Ind. Zool.*

*Gymnopus lineatus*, Dum.\* and Bibr.

*Chitra indica*, Gray: Catal.

Shell remarkably depressed, smooth. [Note. In the living adult no longitudinal central depression is apparent, nor the outline of the costæ, as represented in the figure in *Illustrations of Indian Zoology*.] Above greenish olive, vermiculated and spotted with brown or rust colour; beneath greenish white.

*Habit*.—*Penang*, *Malayan Peninsula*, (*Estuaries*, *Sea Coast*). Rivers in India, Philippine Islands.

At Penang this species is frequently taken in the fishing stakes. The Chinese inhabitants greatly

# REPTILES OF THE

relish this as well as the preceding species of *Gymnopus* as articles of food. Individuals weighing 240 lbs. occur in the Ganges, and others of gigantic dimensions are not uncommon at Pinang. It is very powerful, and of ferocious habits. The largest individual measured:

	Feet.	Inch.
Length of the head, .....	0	6
Do. do. neck, .....	0	5
Do. do. shell, .....	3	1
Do. do. tail, .....	0	4

## FAM. THALASSIDÆ, OR TURTLES, *Dum. and Bibr.*

(2307) *Gen. CHELONIA*. Brogniart.

Body covered with horny plates; fins with one or two nails.

*Sub-Gen. Chelonia libera* (*Chelonées franches*) *Dum. and Bibr.*

Discal shields 13, not imbricate; muzzle short rounded; upper jaw slightly notched in front, toothed on the sides; lower jaw formed of three pieces, and with the edges deeply toothed; the first finger of each fin nailed.

(2308) *CHELONIA VIRGATA* Schweigger.

*SYN.*—Turtle of the Red Sea, Bruce.

*Chelonia virgata*, apud Cuvier, Guerin, Dumeril and Bibron, Gray: Catal.

*Chelonia midas*, Var. D. Gray.

*Chelonia fasciata*, Cuvier, apud Schlegel.

"Pinyu" of the Malays of Pinang.

*Young.*—Head, shell and fins greenish black; margin of the shell and fins and sternum white.

*Adult.*—Head and fins chestnut, scales edged with yellow; shell greenish yellow with chestnut rays and spots; sternum gamboge, or greenish yellow.

*Habit.*—*Malayan Seas.* Teneriffe, Rio Janeiro, Cape of Good Hope, New York, Indian Ocean, Red Sea.

This species is at all seasons plentifully taken in fishing stakes in the straits of Malacca, and is the "Green Turtle" of the European inhabitants of our Malayan settlements, and of the sea-ports of India. In size it equals *Chelonia midas*, Schweigger, which it rivals in flavour. About December and January is the season when the female deposits her eggs in the sandy beach of some sequestered island, and then the fishermen watch during the moonlight nights to "turn turtles."

The eggs are of a spherical shape, about one inch in diameter, covered by a soft hemetransparent membrane of a pale yellow colour. The expert eye of the fishermen baffles the pains with which the turtle conceals her eggs, and prodigious numbers are disinterred.

They are very rich, flavoured like marrow, and will keep for weeks although exposed to the air.

M.M. Dumeril and Bibron have pointed out the differences between the adult of the pre-

sent species and *Chelonia midas*, Schweigger, principally consisting in colours, and in the form of the vertebral and costal shields, to which may be added the comparative greater length of the frontal-nasal shields in *Chelonia virgata*, in which the breadth is one-third of the length, whereas in *Chelonia midas* it is one-half, and these proportions appear to be constant in all ages of the two species. The very young of both greatly resemble each other in colours and shape. Six living young of the present species were all of the following dimensions:

Length of the head, .....

0 <sup>7</sup>/<sub>8</sub> Inch.

Do. do. neck, .....

0 <sup>1</sup>/<sub>8</sub>

Do. do. shell, .....

2

Do. do. tail, .....

0 <sup>2</sup>/<sub>8</sub>

The following slight differences are the result of a comparison between the living young of *Chelonia virgata* and the representation of *Chelonia midas* given by Schœpff Tab. XVII. Fig. 2.

*Chelonia virgata.*

*Chelonia midas.*

- |                                                                                             |                                                                          |
|---------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| 1. Shell cordiform; the length exceeds the breadth by one-eighth.                           | 1. Shell ovate; the length exceeds the breadth by more than two-eighths. |
| 2. 2nd Vertebral shield much broader than 1st, and is altogether the largest of the series. | 2. 1st and 3rd Vertebral of equal demensions.                            |
| 3. 2d costal shield larger than the 3d.                                                     | 3. 2d and 3d costa equal.                                                |
| 4. Sincipital plate broader than long.                                                      | 4. Sincipital plate longer than broad.                                   |
| 5. Breadth of fronto-nasal shields one-third of their length.                               | 5. Breadth of fronto-nasals one-half of their length.                    |
| 6. Each fin with a single nail.                                                             | 6. Each fin with 2 nails.                                                |

*Sub Gen. Chelonia imbricata*, (*Chelonées imbriques*) *Dum. and Bibr.*

Discal shields 13, imbricate; muzzle long, compressed; jaws with the edge straight, not toothed, at the extremity slightly recurved: each fin with 2 nails,

(2309) *CHELONIA IMBRICATA*, (Linne).

*Chelonia caretta*, Temminck, and Schlegel.

"Kûra-kûra" of the Malays of Pinang.

Head brown, scales edged or rayed with yellow; shell yellow, marbled or rayed with rich brown; sternum yellowish white. In the young the areola of the sternal shields black.

*Habit.*—*Malayan Seas*. Atlantic and Indian Ocean.

The largest individual observed was of the following dimensions :

	Feet.	Inch.
Length of the head,....	0	4 $\frac{3}{8}$
Do. do. neck,....	0	3 $\frac{3}{8}$
Do. do. shell,....	1	7
Do. do. tail,....	0	2 $\frac{2}{8}$

*Sub-Gen. Caouana*, (*Caouanes*.) Dum. and Bibr.

Discal shields 15, not imbricate; jaws at the extremity slightly recurved.

(2310) *CHELONIA OLIVACEA*, Eschscholtz : Atlas.

*SYN.*—*Chelonia Caouana*, Var. B. Gray.

*Chelonia dussumierii*, Dum. and Bibr.

*Caouana olivacea*, Gray : Catal.

*Young.*—Above blackish olive, lighter than in the adult; shell and fins edged with pale yellow; sternum pale greenish yellow, washed with chestnut, areolæ blackish.

*Adult.*—Head brown; shell blackish green; some of the marginal scales of the fins yellow; sternum yellow, washed with chestnut; 27 marginal shields; fins with 1 nail.

*Habit.*—*Malayan Seas*. Bay of Bengal, Chinese Seas. This species is at Penang of rare occurrence. A single young individual observed was of the following dimensions :

Length of the head,.....	1 $\frac{7}{8}$	inch.
Do do neck,.....	1	
Do do shell,.....	6	
Do do tail,.....	0 $\frac{7}{8}$	

The shell is broad sub-cordiform, (its length exceeding its breadth by half an inch,) three keeled, the vertebral keel strongest, dentated behind; the marginal shields 27, obliquely placed. The 1st and 4th pair of costals, and the 4th vertebral shield each divided in two pieces.

In a not quite full-grown specimen, in the Museum of the Asiatic Society, the length of the shell is 2 feet 1 $\frac{3}{8}$  inch; its greatest breadth is 2 ft. 0 $\frac{4}{8}$  inch, the length exceeding the breadth by one inch. The vertebral shields are still slightly keeled. The 1st and 4th pair of costals, the 2d left costal, and the 4th vertebral are divided. The central part of the margin is slightly

upwards. The edges of the jaws are not toothed, but they are transparent with fine white vertical lines, which give them a fringed appearance.

The flesh of this, turtle, though relished by the Chinese settlers, is unpalatable to Europeans.

## SAURIA.

FAM. CROCODYLIDÆ, Bonaparte, (ASPIDIOTES, Dum. and Bibr.) *Sub. Gen Crocodilus*, apud Cuvier.

Muzzle oblong, depressed; teeth unequal, the 4th of the lower jaw fitting into lateral notches, and not into hollows of the upper jaw. Skull behind the eyes with two large holes, perceptible through the integuments. Hind-feet with an external dentated crest, and the toes palmated.

(2311) *CROCODYLUS VULGARIS*, Cuvier.—Var. B., Dum and Bibr.

*Crocodilus palustris*, Lesson.

*Crocodilus Vulgaris*, var. E. Gray.

*Crocodilus biporcatus raninus*, Muller, Tab. 3, Fig 7.

*Crocodilus palustris*, apud Gray : Catal.

"Buaya" of the Malays.

Muzzle a little widened, thick, transversally very slightly curved; head covered with angular rugosities; lateral margins of the skull not raised. Above greenish-olive, speckled with black; beneath yellowish or greenish-white.

*Habit.*—*Malayan Peninsula and Islands*. Java, Sumatra, Tenasserim; Bengal, Coromandel, Malabar.

It inhabits not only rivers and estuaries, but also the sea coasts, and may in calm weather be seen floating at a distance of two to three miles from the shore. Although numerous at Pinang and the opposite coast, it appears to be less so than *Crocodilus biporcatus*. Fishermen while working the nets are not seldom attacked by Crocodiles, and would, but for their presence of mind, oftener than they do, forfeit their lives. When seized, they force the fingers into the eyes of the Crocodile, which immediately lets go its victim, who is farther rescued by his comrades.—From 1842 to 1845 amputations from accidents of this description, were unfortunately of no rare occurrence in the General Hospital at Pinang.

Individuals, 15 feet in length are not uncommon; some attaining to 20 feet and upwards are reported to occur.—In rivers a single one will often appropriate to himself a limited district, which if it happens to be in the vicinity of a village, will soon be perceived in the loss of the grazing cattle. Instances of Malays, who, to avenge the loss of a relative, have watched the crocodile, and by diving from below, plunged a Kris into its heart, are on record. The eggs are white, the shell hard, of a cylindrical form, upwards of 3 inches in length, and about 1 $\frac{1}{2}$  inch

# REPTILES OF THE

*Crocodilus porosus*, Schn, apud Gray: Catal.  
 "Buaya" of the Malays.

Upper jaw surmounted by two rugged ridges,  
 each commencing from the anterior angle of the  
 eye; nuchal plates either none, or two very small.  
 Above yellowish green with large black oval spot;  
 keels of the dorsal scales green; beneath greenish  
 white.

*Habit.*—*Malayan Peninsula, Pinang, Singa-*  
*pore* India, Tenasserim, Sumatra, Java, Timor,  
 Seychelle Islands.

This, in the Malayan countries exceedingly  
 numerous species, is of the same habits, and at-  
 tains to the same size as the preceding.

FAM. GECKONIDÆ, Bonaparte, (ASCA-  
 LABOTES, Dum and Bibr.)

*Gen.* PLATYDACTYLUS, Cuvier.

Toes more or less dilated throughout their  
 length, beneath with transverse imbricate plates,  
 either entire or divided by a central longitudinal  
 groove.

(2313) *PLATYDACTYLUS LUGUBRIS*, Dum.  
 and Bibr.

Syn.—*Amydosaurus lugubris*, Gray.

Thumbs nailless; transverse plates beneath all  
 the toes; back finely granular. Above whitish,  
 with black spots.

*Habit.*—*Pinang. Otaheite.*

A single male was captured in my house in  
 the valley of Pinang.

The integuments correspond to the description  
 given by M.M. Duméril and Bibron, to which  
 may be added the following characters: The  
 skin is somewhat loose, forming a slight  
 longitudinal fold on each side of the body,  
 and on the anterior margin of the thigh. The  
 anus is covered by a transversal fold, reach-  
 ing across from the one thigh to the other.  
 There are no femoral pores. The tail is taper-  
 ing, much depressed, convex on the upper  
 surface, flat beneath, sharp at the sides. Near  
 the root, about  $\frac{2}{3}$  of an inch distant from the  
 anus, the skin forms an annular fold, completely  
 encircling that part of the tail. The colour slight-  
 ly differs from that of the Otaheite individuals.  
 The upper parts and the lower surface of the tail  
 from the annular fold are of a buff or pale dust

colour, so closely and minutely dotted with red-  
 dish brown, that the parts have a pale greyish  
 brown appearance. On the loins and between  
 the shoulders are a few distant blackish spots,  
 besides in the latter place appear two short lateral  
 lines, and an indistinct band proceeds from the  
 nostril across the eye to the shoulder. The  
 throat, inner side of the limbs, abdomen and the  
 lower surface of the root of the tail to the annu-  
 lar fold are buff-coloured. The pupil is black,  
 vertical, dentilated, the iris silvery, dotted with  
 reddish brown.

Length of the head. ...  $0\frac{1}{8}$  Inch.

Do. do trunk. ...  $1\frac{3}{8}$

Do. do tail. ...  $1\frac{3}{8}$

"To-ke" of the Malays. [Note. The Malays  
 denominate the family of *Geckotidæ*: *Gekko*,  
*Keko*, *Gago*, *Goke*, evidently Onomatopoeias,  
 in imitation of the cry of these lizards.]

Above ash-coloured with numerous pale orange  
 spots; beneath yellowish white. Between the  
 scales of the back 12 longitudinal rows of large  
 distant tubercles, and six similar on the tail; the  
 latter with minute scales beneath.

*Habit.*—*Malayan Peninsula. Philippine Islands*,  
*Java, Tenasserim, Burmah, Bengal, Coromandel*  
*Coast.*

On the Malayan peninsula this species appears  
 to be less numerous than in the Tenasserim Pro-  
 vinces, where its shrill cry, "To-ke" is nightly  
 heard in houses. The male has two tubercular  
 scales on each side of the root of the tail. The  
 largest individual observed was of the following  
 dimensions:

Length of the head, ...  $1\frac{7}{8}$  Inch.

Do. do trunk, ...  $4\frac{3}{8}$

Do. do tail, .....  $4\frac{5}{8}$

Entire length, .....  $10\frac{3}{8}$

(2315) *PLATYDACTYLUS STENTOR*. N. S.

SYN.—"Toke" of the Malays.

Above light bluish grey with numerous irregu-  
 lar blackish spots, forming on the vertex an an-

# MALAYAN PENINSULA AND ISLANDS.

gle like an inverted V, and on the neck short oblique lateral bands. Beneath pearl-coloured. On the back and sides 10 longitudinal rows of large distant lenticular scales, and 6 similar on the tail; the latter with scutella beneath.

*Habit.*—*Pinang*.

In form and size this species closely resembles the preceding, from which it however differs in the following particulars. The oval nostrils are bordered in front by three scales, viz. the first upper-labial, a smaller rectangular, and a larger pentagonal scale, both of which latter are situated between the nostril and the rostral. Above the nostrils are surrounded by two smaller irregular triangular, and behind by a narrow crescent shaped scale. Of labial scales there are 14 above, 12 below. There are about 72 teeth in each jaw. The eye is very large; pupil black dentilated; iris silvery bluish grey. The ear is very large, obliquely oval without dentilations. The cheeks are much swollen. The scales of the back are small, rounded, hexagonal, becoming more rectangular on the sides. The rows of lenticular scales along the vertebra are smaller than the rest, but not so close as in *P. guttatus*. Behind the mental scale is a pair of large elongated scales, and 5 pentagonal larger appear on each side behind the lower labials. The gular scales are small, polygonal; the abdominal are rounded, hexagonal, not imbricate, and below the root of the tail become somewhat larger. The rest of the lower surface of the tail is covered with scutilla. Above the covering of the tail is like that of *P. guttatus*. On each side of the posterior margin of the cloaca are two very large tubercular-scales, and towards the centre two rather large postanal pores, covered by a loose fold of the skin. Fourteen femoral pores are placed on a slightly angular line. This species is also closely allied to *Platydictylus monarchus*, Schlegel, from which it however readily may be distinguished by the regular rows of lenticular dorsal scales, by its far greater size, and by its loud note. It is not numerous at Pinang. The only individual obtained, from the villa on the Pentland Hills, was a male of the following dimensions:

Length of the head,.....	2 $\frac{3}{8}$	Inch.
Do do trunk,.....	5 $\frac{4}{8}$	
Do do tail,.....	8 $\frac{3}{8}$	

Entire length,..... 1 ft. 4 inch.

(2316) *PLATYDICTYLUS MONARCHUS*, Schlegel, MS.

*SYN.*—*Platydictylus monarchus* Schl. apud Dum. and Bibr.

*Gecko monarchus*, Gray: Catal.

On the back, sides and limbs numerous conical tubercles irregularly scattered among the smaller flat polygonal scales; on the upper surface of the tail 6 to 13 transversal series of small spines; beneath scutell, a sometimes mixed with scuta. Chin with 2 larger oblong scales.

*New-born.*—Above brown, with the dorsal and caudal tubercles (no spines) white; the posterior part of the tail indistinctly white ringed; beneath uniformly paler brown.

*Adult.*—Above buff or ash-coloured or reddish brown, with 8 to 12 pairs of irregularly rounded, distant, dark brown spots along the spine; the head, limbs and sides with numerous more or less distinct, irregular dark brown spots; in some younger individuals the tail with whitish rings. Beneath yellowish white.

*Habit.*—*Malayan Peninsula, Pinang, Singapore, Philippine Islands, Amboyna, Borneo.*

The Malayan Geckonidæ have the power of somewhat changing the ground colour, none however in a greater degree than the present species. In the valley and on the hills of Pinang it is very numerous, swarming at night in rooms, on the walls, and under the ceiling, occasionally giving out a sound, resembling the monosyllable "Tok," repeated six or eight times with increased celerity. The aim of these lizards is by no means unerring; they frequently miss an insect, and fall from the ceiling. Among themselves they are pugnacious, when two or more covet an insect, the successful one has to defend its prize, or give it up to the stronger. The new-born (with umbilical aperture) and adult are of the following dimensions:

	<i>New-born.</i>	<i>Adult.</i>
Length of the head,.....	0 $\frac{3}{8}$	1 $\frac{3}{8}$ inch.
Do do trunk,.....	0 $\frac{5}{8}$	2 $\frac{3}{8}$
Do do tail,.....	1 $\frac{1}{8}$	3 $\frac{1}{8}$

Entire length, ..... 2  $\frac{1}{8}$  6  $\frac{5}{8}$  inch.

*Sub-Gen.* *PTYCHOZOOON*, Kuhl.

Toes webbed to the last compressed joint; thumbs nailless; sides of the head, body, limbs and tail with broad scaly membranes, those of the tail anteriorly scalloped. Male with femoral pores. On the sides scattered tubercles.

(2317) *PTYCHOZOOON HOMALOCEPHALUM*, (Creveld)

*Lacerta homalocephala*, Creveld.

*Gecko homalocephalus*, Tilesius.

*Ptychozoon homalocephalum*, { Fitzinger.  
Wagler.  
apud. Weigmann.

*Pteropleura horsfieldii*, Gray.

*Platydictylus homalocephalus*, Cuv. apud Dum. and Bibr.

*Ptychozoon homalocephala*, Kuhl, apud Gray: Catal.

*Head.*—The ground colour yellowish green olive. Between the eyes and muzzle a double figure, in whitish outline, representing in front a broad arrowhead, posteriorly united by a narrow stalk to a rectangular transversal band, situated in front of the eyes. On the vertex another larger figure, traced in whitish outline, rectangular in front, spreading like a four-rayed star over the occiput. A dark brown band proceeds

## REPTILES OF THE

from behind the eye, across the ear, to the shoulders, where it is lost in the general dark brown colour of the sides of the body. The superior margins of these two lateral bands are white proceeding backwards in zig-zag line, approaching each other over the shoulders, where they join the anterior black transversal line. The lips white. The membranes of the cheeks pale flesh-colour, with dark blue spots, and with the interstices between the scales pale lilac. The pupil vertical, dentilated; the iris rich golden brown.

**Back.** Of the same ground colour as the head, becoming dark reddish brown on the sides, relieved by 4 to 6 distant transversal black dotted lines, on the upper part of the form of the letter M, sending oblique, forwards pointed, lines on the sides. The upper part of the lateral membrane reddish brown; the interstices of the small rectangular scales purple.

**Tail and limbs.** Same ground-colour, as that of the head and back, with broad, distant, indistinctly whitish, transversal bands. On each elbow a whitish ring. Membranes of the tail, limbs and toes are yellowish grey with numerous minute spots of brown, purple, blue and red, which impart a purple, changing appearance to the general colour. The number of the indentations of the caudal membranes varies individually; the posterior part is entire, with waving surfaces.

**Lower parts.** Brownish white, with a few pale brown spots on the throat, inner side of the limbs, in the palms and soles. The tail and its membranes brownish.

**Habit.**—*Pinang Hills*, Singapore, Java, Ramree Island, (Arracan).

As correctly observed by M.M. Dumeril and Bibron, the scales of the female corresponding to those with the femoral pores of the male, have a slight, yet distinct, central depression. The female has a large tubercular scale on each side of the root of the tail, as well as the male. In colour and size the two sexes resemble each other. Two individuals were at different times captured in the villa occupied by Sir William Norris on the Great Hill of Pinang. When the lizard is at rest, the membranes of the cheeks, and the body are kept in close contact with these parts; in leaping those of the body are somewhat stretched out, and all the membranes together then act as a parachute. Also this lizard has in some degree the power of changing the ground colour from a darker to a lighter shade. The apex of the tongue is rounded with a small notch in the centre. A female while in my possession refused insects and water. She deposited a single egg, of a spherical form, about half an inch in diameter, soft, and of a yellowish white colour, which the following day she devoured. A male ate the integuments he had been

changing. The female was of the following dimensions :

Length of the head,....	1	inch.
Do do trunk,.....	2	$\frac{3}{8}$
Do do tail,.....	3	$\frac{5}{8}$

Entire length.  $7\frac{3}{8}$  inches.

In the Museum of the Asiatic Society is preserved a specimen of *Leptophis ornatus*, (Merrem,) in the act of devouring one of the present species. The serpent was captured in the Island of Ramree on the coast of Arracan.

(2318) *Gen.* HEMIDACTYLUS, Cuvier.

End of the toes widened into an oval disk, with a double series of transverse, imbricate plates beneath. From the middle of the disk rise the slender second and third nailed phalanx. A series of scuta beneath the tail.

(2319) HEMIDACTYLUS PERONII, Dum. and Bibr.

SYN.—*Hemidactylus leirus*, Gray.

*Peripia peronii*, Gray : Catal.

Under the chin a large triangular figure, composed of six elongated, towards the sides decreasing, scales; thumbs nailless; male with femoral pores; tail much depressed, very broad at the root, tapering towards the point, (sometimes with a small membrane on each side of the point,) with a series of scuta beneath; pupil vertical, shaped like two rhombs placed with the angles towards each other. [Note. Such is its appearance in the living animal, when the eye is exposed to the influence of light. M.M. Dumeril and Bibron note the pupil being "elliptical," which probably originates in their describing from preserved specimens, although my own in spirits of wine have retained the original form of the pupil.]

Above ash-coloured, labial scales whitish, each with a brown spot; beneath whitish. Iris silvery grey, spotted with brown.

**Habit.**—*Pinang*. Isle of France.

Of two individuals, captured at different times in my house in the valley of Pinang, the larger was of the following dimensions :

Length of the head, .....	0	$\frac{6}{8}$ inch.
Do. do trunk,.....	1	$\frac{5}{8}$
Do. do tail,.....	2	$\frac{3}{8}$

Entire length. ....  $4\frac{6}{8}$  inches.

(2320) HEMIDACTYLUS COCTÆI, Dum. and Bibr.

Thumbs well developed, nailed; [Note. Mr. Gray gives the present species as a Syn. of *Bolitania sublaevis*, Gray, (Catalogue, p. 158.) As the latter species is characterised as having the thumbs "clawless," it cannot be identical with *H. coctæi*,] back with minute granular scales; in some individuals with a few larger ones on the sides; tail broad at the root, tapering, a little depressed; with from 4 to 15 in

# MALAYAN PENINSULA AND ISLANDS.

distinct rings and 6 series of minute spines; beneath with scuta; chin with 4 larger scales; the central pair elongate pentagonal; male with 12 femoral pores; pupil as in *Hemidactylus peronii*.

Above ash-coloured, whitish beneath.

*Habit.*—*Pinang*. Bengal, Bombay.

Of two males observed in houses in the valley of *Pinang*, the larger was of the following dimensions:

Length of the head,..... $1\frac{1}{8}$  Inch.

Do. do. trunk,..... $2\frac{1}{8}$

Do. do. tail,..... $3\frac{1}{8}$

Entire length,.....7 inches.

(2321) *HEMIDACTYLUS FRENATUS*, Schlegel, MS.

SYN.—*Hemidactylus frenatus*, Schlegel, apud Dum. and Bibr.

*Hemidactylus lateralis*, ..  
*Hemidactylus quinquelineatus* } Gray: B.M.

Back with some larger granular scales; tail rounded, tapering above, with 6 series of small spines, scuta beneath; chin with 4 or 6 larger scales; ears very small; pupil as in the preceding species; thumbs very small, femoral pores 26 to 28, disposed on a slightly angular line.

*Young and Adult.*—Buff or ash-coloured, with or without brown spots; some with one or two brown lateral bands, commencing one above the other from the muzzle, interrupted or continued to the tail; the latter in some with distinct brown rings. Beneath whitish or buff.

*Habit.*—*Malayan Peninsula*, *Pinang*, *Singapore*. Amboyna, Timor, Java, Marianne Islands. Ceylon, Bengal.

Assam, [Note. Specimens in the Museum of the Asiatic Society.]—South Africa, Madagascar.

In the Malayan valleys and hills this small species is very numerous. It is of fierce habits, like several other *Geckonidae* destroying its own species. Its normal colour appears to be greyish, which it however has in its power to change. The largest individuals observed were of the following dimensions:

Length of the head,.....  $0\frac{1}{8}$  Inch.

Do. do. trunk,..... 2

Do. do. tail,..... 2

Entire length,.....  $4\frac{1}{8}$

(2322) *HEMIDACTYLUS PLATYURUS*, Schneider.

SYN.—*Stellio platyurus*, Schneider.

*Gecko platyurus*, Merrem.

*Hemidactylus platyurus*, Wiegmann.

*Hemidactylus marginatus*, Cuvier apud {Wagler.  
Weigmann.  
Gray.

*Platyurus schneiderianus*, Gray: Catal.

Sides of the body and posterior margin of the thighs with a loose membrane; tail tapering, de-

pressed, with sharp, fringed margins, with scuta beneath; toes webbed half their length; chin with 4 pentagonal broad scales, placed in pairs, behind each other: 6 femoral pores placed on a continued line.

*Young and Adult.*—Above ash-coloured, in some with a greyish brown lateral band, from the muzzle continued to the tail; the latter with indistinct brownish transversal bands; others irregularly spotted and marbled with blackish brown; pupil and iris as in the preceding species. Whitish beneath.

*Habit.*—*Pinang*. Philippine Islands, Borneo, Java, Bengal, Assam. [Note. Specimens in the Museum of the Asiatic Society].

The individuals were observed in houses in the valley of *Pinang*. In a male the posterior half of the tail happens to be divided so as to appear double; one of the pieces, the continuation of the normal tail, is depressed, slightly fringed, and beneath with the row of scuta continued, the other is cylindrical, somewhat shorter, and above and below covered with minute scales. The largest individual was of the following dimensions:

Length of the head,.....  $0\frac{1}{8}$  Inch.

Do. do. trunk,....  $2\frac{1}{8}$  ..

Do. do. tail,....  $2\frac{1}{8}$  ..

Entire length,....  $4\frac{1}{8}$  ..

(2323) *Gen. GYMNODACTYLUS*, Spix.

Toes not widened into a disk, nor with denticulated margins; all five with non-retractile nails; fifth hind-toe versatile or capable of turning from the others under a right angle.

(2324) *GYMNODACTYLUS PULCHELLUS* (Gray)

SYN.—*Cyrtodactylus pulchellus*, Gray.

*Gonyodactylus pulchellus*, Wagler.

*Gymnodactylus pulchellus*, Dumeril and Bibr.

Head, back and limbs with numerous three sided tubercles among the smaller flat scales; sides of the body with a longitudinal fold of the skin; the anterior upper part of the cylindrical tail with distant rings of rounded, pointed tubercles; beneath a row of scuta. Chin with six scales, the centre pair elongated pentagonal. Males with 36 femoral pores on two not connected lines, between which, in front of the anus, a short narrow, longitudinal furrow. Both sexes with 3 or 4 tubercles obliquely situated on each side of the root of the tail.

*Young and Adult.*—Above rich brownish ochre; the nape of the neck and back with 6 broad transversal bands (the two anterior horse-shoe shaped), of a rich velvety mulberry, or snuff-colour with sulphur or chrome-yellow margins. The tail with 8 or 9 complete rings of similar colour, without the margins. Beneath: throat and belly whitish yellow, or pale brownish, each scale minutely dotted with brown. Pupil vertical,

# REPTILES OF THE

dentilated; iris golden, finely vermiculated with Van Dyke brown.

*Habit.*—*Pinang Hills*. Singapore.

In the male the two rows of femoral pores commence as two short parallel longitudinal limbs, separated from each other by a narrow short furrow, on the sides of which, (vertically), the first five femoral (preanal), pores are placed. In front of the anus the short vertical portions turn right and left under a nearly right angle, continuing the entire length of the thigh, each supporting 13 more femoral pores. The interval between the anus and the latter is partly occupied by a flat, slightly raised triangular space, covered by rather large, imbricate, rounded scales. In the female the two lines of larger scales carrying the femoral pores of the males, are present, each scale having a small shallow, round depression. The short, longitudinal furrow of the male is either wanting or barely distinguishable, but the triangular space with larger scales, in front of the anus, is present. The species appears to be rather numerous on the hills at Pinang, where the individuals obtained were captured in houses, at an elevation of 2,200 feet. The largest male was of the following dimensions:

Length of the head,.....  $1\frac{1}{8}$  inch.  
Do. do. trunk,..... 3  
Do. do. tail,.....  $5\frac{1}{8}$

Entire length... 10 inches.

Its habits offer nothing peculiar: it bites fiercely in defence. In captivity it refuses insects. The integuments, when about being renewed, are piecemeal torn off by the teeth, and devoured. A single egg deposited was of a spherical form, about half an inch in diameter, of a whitish yellow colour. M.M. Dumeril and Bibron assign Bengal as the habitat of this species. The specimens originally described by Mr. Gray, some in the Museum of the Asiatic Society, and a number in my own collection, all are from the hills of Prince of Wales Island (Pulo Pinang.) but no authenticated record exists of this species ever having been observed in Bengal. Another, widely different species of *Gymnodactylus* inhabits Bengal, as yet not published, and only known from three specimens, preserved in spirits in the Museum of the Asiatic Society, where they are marked *Gymnodactylus lunatus*, Blyth. One of these came from Midnapore, the others from Chyebassa. The species somewhat approaches to *G. fasciatus*, Dum. and Bibr. (*Cubina fasciata*, Gray.) The Museum possesses another nondescript species from Almorah, *Gymnodactylus nebulosus*, Blyth, MSS. allied to *G. marmoratus*, (Gray).

The plate of *Cyrtodactylus pmlchellus* in Gray's Illustrations of Indian Zoology is not taken from life, and gives a most inadequate idea of the physiognomy and beauty of the living animal. This should be observed, as M.M. Dumeril and Bibron praise the figure, which evidently has served as

original of their own description, and of copies introduced in illustrative works upon that order of animals.

FAM. VARANIDÆ. Bonaparte, (PLATYNOTES, Dum and Bibr.)

(2325) *Gen.* VARANUS, Merrem.

Scales set side by side, surrounded by an annular series of very minute tubercles; tail above more or less trenchant; on the throat a fold in front of the chest.

*Varani aquatici.*—Dum. and Bibr.

(2326) VARANUS NEBULOSUS, Dumeril and Bibron.

SYN.—*Tupinambis nebulosus*, Cuvier MSS.

*Monitor nebulosus*, Gray.

*Monitor nebulatus*, Schlegel.

*Varanus nebulosus*, apud, Gray: Catal.

Muzzle very elongated; nostrils obliquely cleft, situated half ways between the muzzle and the anterior angle of the eye; lips each with 50 scales; teeth compressed with sharp but not dentilated edges.

*Young*—Above. Ground-colour deep chocolate brown; the head largely marbled with greenish yellow; neck with indistinct obliquely converging gamboge lines; back, sides and limbs with gamboge spots, consisting of one to five scales, (those of the upper margins of the fingers forming continued lines;) sides of the anterior half of the tail, similarly coloured; the double row of scales covering the back of the tail gamboge; the posterior half deep chocolate with two distant (the second subterminal,) indistinct gamboge coloured rings.

Beneath. Ground colour pale chocolate. Chin, throat, chest and four limbs transversely undulated with greenish yellow; abdomen with short, interrupted, transversal yellow bands, consisting of from 4 to 12 scales; hind-limbs with larger similar spots; anterior half of the tail indistinctly marbled with yellowish green; posterior half like the upper surface. Pupil round; iris narrow, golden.

*Adult.*—Above brownish olive with yellow dots; anterior half of the tail yellow with minute square brown spots; posterior half brown and yellow-ringed; margins of the toes yellow. Beneath marbled and barred with brown and yellow.

*Habit.*—*Pinang*. Java, Siam, Bengal.

The only individual observed was a young male, captured in the hills at Pinang, of the following dimensions:

Length of the head,.....  $1\frac{1}{8}$  inch.  
Do. do. trunk,.....  $5\frac{1}{8}$   
Do. do. tail,.....  $9\frac{1}{8}$

Entire length,.... 16

(2327) VARANUS FLAVESCENS, (Gray)

*Monitor flavescens*, Gray.

*Monitor Hardwickii*, Gray, MSS.

*Varanus russellii*, Schlegel. MSS.

*Monitor exanthematicus*, Var. indica, Schlegel.

*Varanus picquotii*, Dum, and Bibr.

*Empagusia flavescens*, Gray: Catal.

Muzzle obtuse; nostrils oval, oblique, nearer the muzzle than the orbit; a series of supraorbital scales larger than the rest; scales of the back distant, bluntly keeled, of the tail and outside of the hind-limbs closer, sharply keeled; toes very short, nails yellow.

Above. Ground-colour light green olive with numerous distant, interrupted, transversal, yellow bands; temples, cheeks, and lips yellow. Beneath yellow; the throat with transversal pale brownish bands.

*Habit.*—*Pinang*. Bengal, Nipal.

A single male observed was of the following dimensions:

	Feet.	Inch.
Length of the head,.....	0	3
Do. do. trunk,.....	1	0 $\frac{5}{8}$
Do. do. tail,.....	1	6 $\frac{1}{8}$
<hr/>		<hr/>

"Beyawak" of the Malays of the Peninsula.

Head very elongated; nostrils oval, nearly transversal, close to the muzzle; a series of supraorbital scales, larger than the rest; teeth with dentilated edges; toes very long. Above. Ground colour dark brown or black; a band on the side of the neck from the shoulder to the eye, 5 to 7 distant, transversal series of separate rings, between which numerous spots or interrupted transversal lines, all yellow or yellowish white; the outside of the limbs and the tail spotted, the latter indistinctly banded with yellow. Beneath yellow, the throat with indistinct transversal black bands and minute spots; the sides of the body and limbs in some individuals with large blackish dentilations.

*Habit.*—*Malayan Peninsula*, *Pinang*. Philippine and Molucca Islands, Amboina, Java, Bengal.

This species is very numerous both in hilly and marshy localities. It is commonly during the day observed in the branches of trees overhanging rivers, preying upon birds and their eggs, and smaller lizards, and when disturbed, it throws itself from a considerable height into the water.—When attacked on level ground, it attempts its escape by running, if possible towards the water. Its quickness however is not so great as to prevent

a man from overtaking it, when it will courageously defend itself with teeth and claws and by strokes of the tail. The lowest castes of Hindoos, capture these lizards commonly by digging them out of their burrows on the banks of rivers, for the sake of their flesh, which by these people is greatly relished. Some individuals attain to nearly 7 feet in length, but the majority are smaller. A female examined was of the following dimensions:

	Feet.	Inch.
Length of the head .....	0	4 $\frac{3}{8}$
Do. do. trunk .....	1	3 $\frac{3}{8}$
Do. do. tail ... ..	2	8 $\frac{3}{8}$

Entire length,..... 4 4  $\frac{3}{8}$

FAM. IGUANIDÆ, Gray, (EUNOTES, *Dumeril and Bibron*.)

SUB-FAM. ACRODONTINÆ (ACRODONTES, *Dum. and Bibr.*)

(2329) *Gen. CALOTES*, Cuvier.

Head quadrangular pyramidal, more or less elongated, with small angular scales of nearly equal diameter. Occipital scale minute. Tongue thick, fungous, rounded, with the apex slightly notched. In the upper jaw 5 incisors and 2 canines. Nostrils lateral, pierced through a plate situated close to the muzzle. No transversal fold on the throat, sometimes with a large longitudinal fold on both sides. A gular pouch varying in size. A crest from the nape of the neck to the tail. Scales of the sides of the trunk homogeneous, imbricated in oblique series. No femoral pores.

*Sub-Gen. BRONCHOCELA*, Kaup.

Scales of the trunk in oblique series, inclined backwards, their points directed downwards. Posterior part of the sides of the head not swollen.

(2330) *BRONCHOCELA CRISTATELLA*, (Kuhl.)

*Lacerta mexicana strumosa*, &c. Seba, 89, 1.

*Agama cristatella*, Kuhl.

*Agama gutturosa* Merrem.

*Bronchocele cristatella*, Kaup, apud Dum. and Bibr.

*Agama moluccana*, Lesson, apud Schinz.

*Calotes gutturosa*, Guerin.

*Calotes cristatellus*, Schinz.

*Calotes gutturosus*, Weigmann.

"Gruning" of the Malays of the Peninsula.

Cervical crest (6 to 10 scales,) abruptly decreasing on the anterior part of the back; scales of the side of the trunk keeled, scarcely half the size of those of abdomen; behind the posterior angle of the orbit 3 to 5 flattened scales, pointing outwards, forming a minute longitudinal crest.

*Normal colours.* Beautiful grass-green, lighter beneath, entirely, or partially changeable to light grey, greyish olive, greenish brown, or blackish, sometimes with orange spots, or with indistinct black network; large isolated round spots on the head or back, or the lips, eyelids, or mar-

# REPTILES OF THE

gins round tympanum, momentarily black; sometimes with transversal distant brown bands, particularly on the tail. [Note. During life there is no trace of blue, or even bluish green about this lizard, but after death it sometimes acquires this colour from the effects of spirits of wine, to which circumstance must be attributed the denomination of "Blue Calotes," Gray, in Griffith's edition of Cuvier. Vol 9, p. 55.] Scales of the outside of the limbs and feet edged with brown. Pupil circular; iris brown with a narrow golden ring.

*Habit*.—*Malayan Peninsula, Pinang, Singapore.* Amboyna, Island of Buru, Java, Sumatra:

This species is very numerous in the Malayan countries both in the valleys and on the hills. It moves and leaps with great quickness among the branches of the trees. The most striking feature is the great power of suddenly changing its colours. The Malayan denomination of this species is "*Gruning*," which in Marsden's Dictionary is translated "a species of lizard, which changes its colour as it is affected by fear or anger; theameleon." No cameleon however appears to inhabit the Malayan countries, but the present lizard passes under that name among the European inhabitants. One of the largest males was of the following dimensions:

	Feet.	Inch.
Length of the head,...	0	1 $\frac{3}{8}$
Do. do. trunk,..	0	3 $\frac{5}{8}$
Do. do. tail,....	1	2 $\frac{5}{8}$
Entire length,...	1	7 $\frac{1}{8}$
Those of the intestinal canal:		
Small intestines, .....		3 $\frac{4}{8}$ inch.
Large, ,, .....		1 $\frac{1}{8}$
Cæcum, ,, .....		0 $\frac{4}{8}$

The stomach is cylindrical, simply a continuation of œsophagus without fundus, but separated from the small intestines by a valve. In several dissected it contained nothing but mucus. The length of œsophagus and the stomach together was 1  $\frac{4}{8}$  inch. The anterior part of the small intestines is widened till about a quarter of an inch from the pyloric valve, where ductus coledochus enters. Cæcum is very widened, more so than any other part of the canal, of a crescent shape.

(2331) *Gen.* LOPHYRUS, Dumeril.

Head triangular, more or less elongated, shelving in front; orbital edge arched or angular; nostrils lateral, circular, or oval; tongue papillary, rounded and very slightly notched at the point; in the upper jaw 5 incisors and 2 canines; tympanum superficial; skin of the throat lax, forming in some a scarcely perceptible, in others a highly developed pouch, and an angular cross fold in front of the chest; neck, trunk and tail compressed, with a crest, generally most elevated on the nape of the neck; scales of

the trunk rhombic, subimbricate, unequal, (with scattered larger scales); femoral pores none.

(2332) LOPHYRUS ARMATUS, (Gray).

*Agama armata*, Gray.

*Calotes tropidogaster*, Cuvier. [Note. By mistake: *Calotes lepidogaster*, Regne anim. 1829. T. ii. p. 39.]

*Acanthosaura armata*, Gray.

Orbital edge slightly angular, with a long spine at its posterior extremity; no spinous tubercles on the occiput; on each side of the nape of the neck, immediately above the ear, another long spine, surrounded with 5 to 6 shorter ones, at its base, from whence proceed obliquely over the temple and cheek a curved series of 18 larger polygonal, keeled scales; tympanum thick, circular; on the neck a crest of 8 to 12 long spines, surrounded with numerous smaller ones at the base; at a short interval the dorsal crest, the anterior 5 to 6 spines of which are very long, the rest rapidly decreasing towards the tail; gular pouch very small, not toothed, with scales of equal size; tail subtriangular, with a toothed crest above.

Above. Head chestnut; trunk and limbs blackish green, with a black transversal band in the interval between the cervical and dorsal crests, continued over the shoulders, with numerous pale yellowish white, black-edged, rounded spots, assuming the shape of transversal bands on the limbs and the tail; the larger single scales on the sides, limbs and tail clear sky-blue; from the orbit over the lip 5 to 6 radiating, black lines. Beneath yellowish white. Pupil circular, iris brown, with a narrow golden ring.

*Habit*.—*Pinang, Singapore.* Cochin China.

At Pinang, this species appears to be very local, and not numerous: two individuals examined were obtained from spice plantations in the valley. They were very active and fierce, possessed in a slight degree the power of changing the ground colour to a lighter hue, and in captivity refused food and water. In a female were found 13 eggs of a yellowish white colour, of an oval shape,  $\frac{5}{8}$  inches in length. The stomach contained fragments of leaves and twigs, and a quantity of earth and lime. The latter probably originated from the lime water, with which the spice-trees are copiously sprinkled, to secure them against the attack of insects. The dimensions of the lizard were:

Length of the head,.....	1 $\frac{1}{8}$ Inch.
Do. do. trunk,.....	3 $\frac{5}{8}$
Do. do. tail,.....	6

Entire length, ... 10  $\frac{1}{8}$

Of the intestinal canal:

Small intestines, ...	7 $\frac{4}{8}$ Inch.
Large, .....	1 $\frac{1}{8}$
Cæcum, .....	0 $\frac{4}{8}$

The stomach capacious, with thick parietes. The first portion of Duodenum is much widened

# MALAYAN PENINSULA AND ISLANDS.

till within half an inch from Pylorus, where Ductus coledochus enters. Cæcum is of a crescent-shape, much widened, as well as the large intestine.

## (2333) *Gen. DILOPHYRUS*, Gray.

Head four-sided. Forehead rather concave, face-ridge high. Eye brows rounded. Occiput with 3 or 4 larger tubercles on each side.

Parotids unarmed. Nape and back with a crest of high compressed scales, with series of smaller scales at their base. The throat rather lax. [Note. Add: *with a compressed pouch minutely toothed in front.*] with a cross fold behind, [Note. *Questionable*] extending up the front of the shoulders. Scales of the back small, rhombic, equal; of the belly rather larger, smooth. Tail compressed, keeled and toothed above, with 2 series of elongated keeled scales beneath. Femoral and preanal scales none.

## (2334) *DILOPHYRUS GRANDIS*, Gray. (Pl. XX).

*Habit.*—*Pinang Hills*. Rangoon.

As the only published characters of this species leave its identity with the Malayan somewhat doubtful, they are here preposed.

“*Olive green; sides white spotted, beneath whitish; tail black-banded; head with lines of rather larger scales; crest very high, formed of broad compressed close-set scales, with 3 or 4 series of scales on each side, of the base, interrupted over the shoulders.*” (Gray: *Catalogue of the Specimens of Lizards, &c* p. 239.)

*Form.*—The head is elongated, four-sided pyramidal, its greatest height and breadth being equal, and less than one half of the length. The muzzle is narrow, rounded, depressed. The upper surface of the head is very sloping, with a narrow furrow between the arched orbital parietes; the forehead depressed or concave. The scales are polygonal, keeled; those of the margin of the orbits and forehead larger, imbricate, forming a sharp ridge; four similar scales form a short ridge in the centre of the forehead, close to the muzzle. Behind the orbit, over tympanum, and on each side of the nape of the neck are similar short, oblique ridges, each composed of 5 larger pointed tubercular scales. The rostral shield is very broad, narrow, triangular; the mental, is much smaller, pointed, triangular, with two large polygonal scales on each side. The upper jaw is covered with 26, the lower with 24 elongated, narrow, rectangular scales.

### *Dentition.*

6	1—1	14-14	36.
Incis. —; Canin. —; Molar. —			
4	1—1	14-14	34.

The incisors and anterior molars are very small; the latter gradually increasing in size, flat, sharply edged, bluntly tricuspidate. The tongue is thick, flattened, very slightly notched in front,

the anterior half spongy, the posterior with large backwards pointed papillæ.

The nostrils are nearly circular, pierced, in a large oval scale, in front of which 3 scales intervene between the rostral. The eyes are large, sunk in the orbits, the pupil circular, black; the iris blue with golden spots and a narrow ring. The eyelids are covered with very minute polygonal, tubercular scales. Each tarsus with a double row of scales, the inner one of small, polygonal, tubercular; the outer one of rhombic, flat, with the angles overlapping, so as to give the free margin a toothed appearance. The tympanum is large circular. The skin of the throat is very lax, forming a compressed pouch, the anterior margin of which is slightly toothed, owing to the series of scales overlapping each other. But there is during life no trace of any “crossfold behind, extending up the front of the shoulders.” The scales of the neck and back are very minute, rhombic, or subrectangular, smooth, increasing in size and becoming imbricate on the sides, abdomen, limbs and throat. On the neck is a high arched, toothed crest, composed 26 large ensiform scales, the 13 anterior gradually increasing in length, the rest decreasing. The base of the crest is supported by two parallel, slightly arched series of rectangular scales, much larger than those of the rest of the body, but those of the upper series double the size of those of the inferior. The dorsal crest commences at a short interval a little behind the shoulders. In shape and component parts it resembles the former, but is double the extent, consisting of 45 scales, all of which however are inferior in height to those of the cervical crest, which, as well as the somewhat lower, sloping level, renders the dorsal crest less conspicuous than the former. The skin is somewhat lax on the sides of the body, leaving the ribs visible. The tail is very much compressed, attenuated elongated. Its sides are covered with rather large, smooth imbricate, rhombic scales. The anterior third of the upper margin is toothed, composed of a single row of large, gradually decreasing, sharply keeled scales. The other two thirds are covered by two rows of keeled scales, thus giving the posterior part of the tail a bidentated appearance. The lower surface of the tail is covered by two series of large, gradually decreasing, imbricate, keeled scales, giving it a bidentated appearance. The limbs are slender; the anterior little more than half the length of the posterior, and the toes very short. The posterior 4th toe is excessively long. The palms and soles are covered with minute, pointed, rough scales; the toes above and beneath with sharply keeled, imbricate, rhombic scales. The claws are large, trenchant, curved.

*Colours.*—The ground-colour of the head, neck, throat, gular pouch, and the chest is impure gamboge, the scales edged with brown. The eyelids dark brown, the tarsi buff. A dark

# REPTILES OF THE

blue triangular streak proceeds from the anterior angle of the orbit to the nostril; another is placed parallel with the upper labial scales, which as well as the lower are of a pale blue, as also the tympanum. From the labial scales and tympanum on each side across the throat, the pouch, and the sides of the neck, proceed 7 oblique, undulating, dark blue bands. The tympanum is enclosed by two oblique broad, purple-brown bands, which join each other under an angle at the anterior extremity of the cervical crest, where a third broad, longitudinal purple-brown band commences, proceeding over the side of the neck, then expanding, covers the back and the upper half of the sides of the body, where its lower margin describes two large curves. The lower part of the sides are of a deep lilac, changing on the abdomen to bluish white. On the sides of the body and on the abdomen appear several oblique series of lozenge-shaped spots: a few on the brown portion of the sides of a deep Indian red, the rest bright gamboge. The cervical and dorsal crests are mulberry-brown; the former with the upper half of each of the first 13 scales light-green; the latter with the upper half of the first 10 scales pale yellow. The scales at the base of the crests partake of the general colour, but many of them have a pale yellow spot. The tail is above and beneath with alternate broad rings of impure white, the scales edged with brown, and purple-brown, changing to black on the posterior half. The legs, feet and toes are dark purple-brown with indistinct transversal yellowish bands.

Dimensions.	Foot.	Inch.

Entire Length,... 3 $\frac{1}{8}$  inch. 6 inch.

The only individual examined, was captured on a botanical excursion by Sir William Norris on the Pinang Hills, on the bank of a mountain stream, at an elevation of about 2,000 feet. It appeared slow in its movements, of general sluggish habits, showed no power of changing colours, and in confinement it refused insects, vegetable food, as well as water. After having been preserved in rectified spirits of wine for upwards of 3 years, the specimen has retained the original brown and white colours and the Indian red spot; but the yellow, light-green and light-blue have

changed to whitish, and the dark blue marks to blackish.

Although the colours in this state do not agree with those given by Mr. Gray, apparently though not stated, taken from a preserved specimen, the peculiar distribution of the markings correspond, and induce me to believe in the identity of the animals.

(2335) *Gen. DRACO*, Linne, apud Dumeril and Bibron.

Head triangular, obtuse in front, slightly depressed, covered with small scales of unequal diameter.

Three or four incisors and 2 canines in the upper jaw. Tongue spongy, thick, rounded, entire. [Note.—In the following species the tongue is minutely, yet distinctly *notched*] Tympanum hidden (i. e. *Dracunculus*, Weigmann.) in some, visible in others. In the centre of the throat an elongated vertical pouch; on each side a smaller horizontal. In general a small cervical crest. [The female of *Draco fimbriatus*, Kuhl, (i. e. *Draco abbreviatus*, Gray,) *D. volans* and *D. maculatus* differs from the male in having no cervical crest, and in having a smaller, less elongated gular pouch.] Trunk depressed, with a lateral membrane, supported by the spurious ribs. No femoral pores. Tail very long, thin, angular, lightly depressed at the root.

*A. Tympanum visible, metallic iridescent.*

(2336) *DRACO VOLANS*, Linne.

*Draco volans* apud Gmel., Latr., Gray.

*Draco Præpos*, Linné, apud Gmelin.

*Draco major*, Laurenti.

*Draco minor*, Laurenti.

Le Dragon, Daubenton, Laccpede, Bonnat.

Flying Draco, Shaw.

*Draco viridis*, Daudin, apud Merr., Kuhl, Wolf, Wagler.

*Draco fuscus*, Daudin, apud Merr., Kuhl.

*Draco bouroumiensis*, Lesson?

*Draco daudinii*, Dumeril and Bibron.

"Chichak terbang" or "Kubin" of the Malays.

Scales of the back rhomboidal, imbricate, indistinctly keeled; of the throat granular, of equal size; the adult male with a small cervical crest; tongue minutely notched in front; gular pouch of the male very long, narrow, nearly double the length of the head; of the female shorter, broad triangular.

*Adult male and female.* Head metallic brown or green, with a black spot between the eyes. Back and inner half of the wing-membrane varied with metallic, iridescent dark brown and rose-colour, in some disposed in alternate transversal bands, with numerous black spots and short irregular waved or zigzag lines. Limbs and tail in some with rose-coloured transversal bands. Sides of the neck and lips also rose coloured with black spots. Cheeks and eyelids silvery-white or sky-blue, the latter with short radiating black lines. Throat and gular pouch bright

yellow, the former dotted with black; lateral pouches yellow or silvery rose, dotted with black. Outer half of the wing membrane black with indistinct transversal bands, composed of large, sometimes confluent, spots of silvery rose or whitish colour; the margins appearing as minutely fringed with silver. Beneath either whitish yellow or pale sky blue with metallic lustre; the membrane largely, the abdomen in some minutely spotted with black or brown. Iris hazel, with a golden narrow ring. *Young* of the same more vivid colours, with a series of double black spots along the spine of the back, and some scattered on the sides.

*Habit.*—*Malayan Peninsula, Pinang.* Philippine Islands. Borneo, Java.

The transcendent beauty of the individually varying colours, baffles description. Such as are current of this and other species, appear to have been taken from preserved specimens. As the lizard lies in shade along the trunk of a tree, its colours at a distance appear like a mixture of brown and grey, and render it scarcely distinguishable from the bark. Thus it remains with no signs of life except the restless eyes, watching passing insects, which, suddenly expanding the wings, it seizes with a sometimes considerable, unerring leap. It is but on close inspection, exposed to the light or in the sun that the matchless brilliancy of its colours appears. But the lizard itself appears to possess no power of changing them. This species is numerous on trees, in valleys and hills. The female, apparently less numerous than the male, carries 3 to 4 eggs of an oval cylindrical shape,  $\frac{3}{8}$  of an inch in length, and of a yellowish white colour.—Of a number examined none exceeded the following dimensions:

Length of the head,..... $\frac{7}{8}$ . 0 $\frac{1}{2}$  Inch.

Do. do trunk, ... .. 2 $\frac{1}{2}$

Do. do. tail,... .. 4 $\frac{1}{2}$

—  
7 $\frac{1}{2}$

B.—*Tympanum hidden by scales* (DRACUNCULUS, *Weigmann*).

(2337) DRACO MACULATUS, Gray.

Syn.—*Dracunculus maculatus*, Gray.\*

\* *Note.* ["Grey, black-spotted; wings black-spotted; throat grey; pouch of the male elongate; scales of the back rather unequal, rhombic, keeled; of the sides rather smaller; sides with a series of large keeled scales; ears rather sunk, with unequal flat scales; tail slender, with a central keel above, and 5 more small ones on the sides, base dilated, with 5 nearly equidistant equal keels above."—*Catalogue of the Specimens of Lizards, &c.*, p. 236]

*Habit.*—*Pinang.* Tenasserim.

*Form.*—This species closely resembles *Dracolineatus*, Daudin, (*Dracunculus lineatus*, *Wiegmann*), from which it differs in the following particulars. The adult male carries

a very elongated, pointed gular pouch, double the length of the head, and a slightly elevated cervical crest, consisting of 6 to 8 pointed tubercular scales, and continued along the anterior half of the back in the shape of a ridge composed of a raised fold of the skin. The *female* has neither cervical crest nor dorsal ridge, and her gular pouch is much reduced, its length being about one half of the length of the head. Both sexes have the following characters in common. From each side of the neck commences a series of spinous scales, sometimes close together on one side, distant on the other, which, increasing in size and becoming more distant, continue along the side of the body, where they deviate outwards, marking the origin of the wings, and again converge towards the root of the tail, where they terminate. The scales of the back are generally smooth, consisting of smaller polygonal, mixed with some larger rhombic, indistinctly keeled, imbricate scales. In some individuals the latter are disposed so as to form a series on each side of the dorsal spine. The supra-orbital margin has from 3 to 4 large pointed tubercles, of which but the one situated at the posterior angle appears to be constant. The scales of the neck and throat are small granular, from which those covering the tympanum differ by being larger, flattened and polygonal. The tubercles of the throat and neck, and many of the scales of the back, wing membranes, and the limbs, have each a minute rounded cavity at the point, discernible by a lens. The pouches, chest and abdomen are covered with rhombic, imbricate, keeled scales without apical cavities. Each jaw has 16 labial scales. The tail long, very broad at the base, particularly in the male, suddenly tapering, rounded above, and covered with strongly keeled, imbricate, rhombic scales. The first large ones of the lowest series of the root form a more or less conspicuous toothed crest. The lower surface is flattened, with scales like the upper. The apex of the tongue is notched.

*Dentition.*

4	1—1	15.—15
Incis.—	Canin. ———	Molar ———
2	1—1	15.—15

*Colours.*—This species bears so close a resemblance to *Draco volans*, that it is scarcely possible to point out any difference. The upper parts of the body are metallic greenish-brown, varied with golden rose-colour or isabella, indistinctly dotted and lined with black. The wings are golden isabella with transversal black bands, formed by series of black rounded spots, either separate or confluent on the inner half, but blending into one another on the outer-half. In some individuals numerous undulating golden rose-coloured or buff lines longitudinally intersect the bands. The margins are finely fringed with silver. The limbs and tail are indistinctly ringed with black or brown. A black spot on the vertex, between the eyes, appears to

be constant also in this species. The gular pouch and the throat are bright yellow, the latter in some dotted with pale brown. The chest and abdomen whitish yellow in some, bluish white in others. The under surface of the wings is of the latter colour, in some with single large rounded black spots near the margins, independent of the upper markings, which may be distinguished through the hemitransparent membrane.

Of this species but four, of which 2 males were received from Sir Wm. Norris. They were all from the Hills of Pinang; [Note. The Museum of the Asiatic Society possesses two females, obtained by the late Dr. Spry in the Tenasserim Provinces.] none exceeded the following dimensions:

Length of the head,.....  $0\frac{5}{8}$  inch.  
Do do trunk,..... 3  
Do do tail,.....  $5\frac{2}{3}$

—  
 $8\frac{7}{8}$  inches.

The intestinal canal of a female measured:

Small intestines,..... 3 inches  
Large „ .....  $0\frac{7}{8}$   
Cæcum „ .....  $0\frac{2}{3}$

The capacious stomach contained remains of insects, particularly of the gigantic black ant, inhabiting the Malayan hill forests. The first portion of Duodenum is much widened till within a quarter of an inch from Pylorus, where Ductus coledochus enters. Coecum is of a short crescent shape, much widened as well as the large intestine. In the abdominal cavity appeared 5 eggs, of an oval form, yellowish white colour, each half an inch in length.

(2338) *Gen. LEIOLEPIS, Cuvier, apud Dumeril and Bibron.*

Head sub-pyramidal quadrangular with minute polygonal, tubercular scales. Tympanic membrane a little sunk. Tongue scaly on the anterior, papillary on the posterior half, apex bifid. Chest with a transversal fold in front. Two canines in each jaw. Trunk sub-cylindrical with granular scales above; beneath with larger, smooth, imbricate, rectangular scales. Femoral pores. Tail conical, very long; the root broad and depressed, the rest excessively slender.

To these characters it will be necessary to add: *Skin of the side of the trunk excessively lax, capable of being expanded into a large wing-like membrane by means of the six anterior, very long, spurious ribs.*

(2339) *LEIOLEPIS BELLII (Gray.)*

SYN.—*Uromastix bellii*. Gray

*Uromastix belliana*, Ill Ind Zool\*

*Leiolepis guttatus*, Cuvier, apud { Guerin.  
Dumeril  
& Bibron.

*Cynosaurus punctatus*, Schlegel.

*Leiolepis bellii*, Gray. Catal.

[Note. In the supposition that this incorrectly drawn and coloured figure has been taken

from the living animal, M.M. Dumeril and Bibron have been led to publish an erroneous description and figure. The last description of this species of Mr. Gray appears to be founded on the same authority. It runs thus: "Olive with black edged white spots and a black edged white streak on each side, beneath whitish." *Catal. &c.*, p. 263.]

Ground colour, above blackish-grey; the back and sides with 7 parallel lines of pale sulphur colour, edged with black, the 2nd from below, the 4th and 6th composed of more or less confluent spots, the other 3 of distant round spots. The expanded membrane black with 7 or 8 broad distant, transversal bars of a brilliant orange. The tail above with numerous small pale yellow spots. The forelegs with orange coloured rounded spots, some of which tipped with azure; the hindlegs minutely spotted with yellow. The throat pale azure; abdomen pale orange, marbled with broad bluish black veins; the tail beneath pale yellowish white. The lower eyelid is pure white; pupil circular, iris hazel with a narrow golden ring.

*Habit.*—*Malayan Peninsula, Pinang. Cochinchina.*

The head is covered with small elongated polygonal keeled scales; the upper jaw with 26, the lower with 18 to 20. The mental shield is elongated polygonal; the upper part of the sides is joined to the first lower labial scales; the centre part is on each side in contact with the first of series of 13 to 15 elongated polygonal scales, which follow the tract of the labial, between which there is a narrow intervening space covered with smooth polygonal scales, larger than those of the rest of the throat. The back and wing membranes are covered with minute granular scales, the abdomen with larger smooth rhombic scales. Those of the tail above and beneath are verticillated, rectangular subimbricate, and strongly keeled. The tongue is thick, fungous, not scaly as incorrectly represented, with the tip much flattened, free and slightly extensile, divided in two laterally compressed sharp points.

The molar teeth are tricuspidate, increasing in size, the anterior being the smallest. In the adult they are much worn and incrustated with brown tartar, like the teeth of *Semnopithecus* and *Ruminantia*.

*Dentition.*

4 1—1, 12-12  
Incis —; Canin, —; Molar —,  
1—1 1—1 11-11

The nails are long, lightly arched, of a pale yellowish horn-colour. The wing membrane in a state of repose appears like a longitudinal loose fold, extending along each side from the axilla to the inguinal region. Expanded the external margin becomes arched, the trunk and the membranes forming a greatly flattened oval disk,

## MALAYAN PENINSULA AND ISLANDS.

strongly contrasting with the bulky appearance of the parts in a state of repose,) resembling the hood of *Naja*. The transversal diameter of the disk across axilla and the inguinal region is  $1\frac{1}{8}$  inches; across the centre  $2\frac{3}{8}$  inches. Like the mechanism of the Genus *Draco*, the membranes are expanded by means of the very long six anterior pairs of spurious ribs, which the lizard has the power of moving forward under a right angle with the vertebral column. The six posterior ones are excessively short, and though equally moveable, do not appear materially to assist in expanding the membranes. The latter are used as a parachute in leaping from branch to branch, after which they immediately resume their state of repose. Sudden fear, or anger will also cause a momentary expansion. The femoral pores are situated on a series of rather large rhombic scales on each thigh. In a number of twelve adult individuals the pores varied from 13 to 19 on each thigh. In the specimens in the Paris Museum, described by M.M. Dumeril and Bibron, there are from 20 to 24 on each thigh.

This species appears to be numerous, but local. Twelve were at one time obtained from a spice plantation in Province Wellesley, some of which were in the act of changing the integuments. They were very active and swift, more so than their rather heavy make would induce to believe, and they would bite and scratch when handled, although among themselves in a spacious cage, they appeared peaceable, and patiently submitted to being trodden, or run over by a neighbour, about ascending the perch. The Malay, who brought the lizards, asserted they were frugivorous, and might be fed with soft fruit and boiled rice, which was perfectly true. In one immediately examined, the stomach and intestines contained rounded seeds of various kinds from the smallest size to that of a large pea, and vegetable fibres. [Note. The latter, however, as well as sand and fragments of stones, also occur in carnivorous and insectivorous lizards, as well as serpents, which swallow these substances to stimulate digestion.]

The rest refused insects and different kinds of fruit, but during the several month's confinement each would daily eat a little boiled rice, and occasionally take water. Of these none exceeded the following dimensions.

	Ft.	Inch.
Length of the head,....	0	$1\frac{1}{8}$
Do. do trunk,...	0	$4\frac{2}{8}$
Do. do tail,.....	1	0

Entire length,....	1 foot $5\frac{3}{8}$ Inch.
Length of the intestinal canal:	
Small intestines,....	$5\frac{5}{8}$ Inch.
Large do. ....	3
Cæcum,.....	$0\frac{2}{8}$

The stomach is of a lengthened pyriform shape, one inch in length; Duodenum, narrow,

receives Ductus coledochus at  $\frac{3}{8}$  inch distance from Pylorus.—Cæcum is very short, nearly circular. The large intestine is sacculated, terminating in a short simple rectum.

(2340) *LEIOLEPIS REVESII*.

There seems to be reason to believe that *Leiolepis revesii* \* Gray, inhabiting "China" and Arracan, is also found on the Malayan Peninsula.

\* [Note. Syn.—*Uromastix revesii*, Gray.—"Olive with a series of bright red spots on each side." (Griffith: Animal Kingdom, IX p. 62.) Such was the only account of this species at the time of the publication of *Herpétologie Générale*, where it is not introduced. Mr. Gray's latest description runs thus: "Olive with longitudinal series of pale whitish spots; when alive blackish, with orange spots on the back, and a series of bright red spots on the sides.—China." (Catalogue &c. p. 263).

The Museum of the Asiatic Society possesses an adult male and a young specimen, sent from Arracan by Capt. Phayre. The form resembles in every particular that of *Leiolepis guttatus*, from which the present species principally differs by its colours, larger heavier make and size. Each jaw is covered by 20 scales. From the mental scale proceeds a series of 10 larger scales on each side below the labial. On the throat appear 2 or 3 strong transversal folds, of which the anterior commences from the posterior margin of the tympanum. The tail is covered with keeled verticillate scales as in *L. guttatus* but not with "rings of smooth scales" as Mr. Gray's generic character states.

## Dentition.

*Tiliqua duvaucellii*, Cocteau.  
*Eumeces punctatus*, Weigmann, apud Dum and Bibr.  
*Riopa hardwickii*, Gray: Catal, (Young.)

Trunk individually varying in length; limbs very small, giving the lizard a blindworm-like appearance; tail very thick at the root, fusiform, tapering to a very sharp point, its length varying from one to two-thirds of the entire length of the animal. On the anterior margin of the ear a small tubercle. Above metallic chestnut, or greenish bronze, in some with 6 or more or less distinct, dotted, black lines along the back, or with the two rows of scales nearest each side of a lighter shade than the ground colour, thus forming two lighter longitudinal bands. From the nostril to the middle of the side of the tail a black or brown band, with numerous small white spots on the sides. Limbs outside dotted with white. Beneath sulphur-coloured, in some the throat and tail minutely dotted with black. Iris dark brown, with a narrow, circular, golden ring.

*Habit.*—*Malayan Peninsula, Pinang, Singapore.* Malabar and Coromandel Coast, Bengal.

The variety described above, is numerous in the Malayan countries, both on hills and in valleys. Of several the largest individual was of the following dimensions:

Length of the head,.....	0 <sup>3</sup> / <sub>8</sub> Inch.
Do. do. trunk.....	2 <sup>1</sup> / <sub>8</sub>
Do. do. tail.....	1 <sup>7</sup> / <sub>8</sub>
Entire length,.....	4 <sup>3</sup> / <sub>8</sub>

(2344) *Sub-Gen. EUPREPIS, Wagler.*

Nostrils pierced through the posterior part of the nasal shield; two super-nasal; palate with a more or less deep triangular incision; pterygoid teeth; scales keeled.

(2345) *EUPREPIS RUFESCENS, (Shaw.)*

*Lacerta maritima maxima*, &c. Seba II, Tab 105, Fig. 3.

*Lacerta rufescens*, Shaw, III, P. 1, P. 258.

*Eumeces rufescens*, Weigmann.  
*Tiliqua carinata*, Gray.  
*Tiliqua affinis*, Gray, (Young).  
*Euprepes sebæ*, Dumeril at Bibron.

Body strong; limbs proportionate; tail rounded, slightly compressed, little exceeding half the entire length. Scales of the back and sides: in the young with 5 to 7 keels; in the adult the dorsal scales with 3 to 5 keels, the rest smooth. The anterior margin of the ear with 3 or 4 minute lobules. Lower eyelid with a series of 4 or 5 larger, square scales. Pterygoid teeth minute, few, hid in the palatal membrane, forming a short line on each side of the triangular incision of the palate.

*Habit.*—Sandwich-Islands, Philippines, Timor, Celebes, Borneo, Java, Coromandel, Bengal.

VAR. D. Dumeril and Bibron.

Above. Ground colour shining bronze with 5 to 7 zigzag, or dotted black lines, in some continued on the tail; sides with many of the scales black, with a square white spot in the middle, in some arranged so as to produce numerous, distant, transversal bands. The margins of some or all the shields of the head black. Beneath sulphur coloured. Iris black with a golden circular ring.

*Habit.*—*Malayan Peninsula, Pinang, Singapore.*

VAR. E., Dumeril and Bibron.

Above uniformly shining bronze; sides in some sprinkled with blood red; rest like the preceding.

*Habit.*—*Same localities.*

VAR. F., Dumeril and Bibron.

Above uniformly shining bronze; the anterior half of the sides with a broad blood-red stripe, which in specimens preserved in spirits of wine changes to whitish, or disappears; the posterior part of the sides of the body and the anterior of the tail in some with square skyblue spots in the middle of some of the scales; rest like the preceding.

*Habit.*—*Same localities.*

These three varieties are exceedingly numerous in the hills and valleys of the Malayan countries. They may be seen basking in the sun, in bamboo hedges, or on trees, and they fearlessly enter houses in pursuit of insects, in which they display great agility. The female deposits 6 to 12 yellow white, oval, cylindrical eggs, half an inch in length. Nearly all have on the lower two-thirds of the tail a series of large scuta. In one individual observed the last two-thirds of the

# MALAYAN PENINSULA AND ISLANDS.

back of the tail was covered with a single series of very broad scales, of which each of the anterior had 15 to 16 keels. In another the tail had been lost near the root, and reproduced by a pyramidal, soft, naked process,  $\frac{3}{8}$  inch long, with circular folds like those of the body of *Ichthyophis*.—*Var. F.* appears to exceed the others in size: the largest was of the following dimensions:

Length of the head,.....  $0\frac{5}{8}$  Inch  
Do. do. trunk,.....  $3\frac{4}{8}$   
Do. do. tail,.....  $4\frac{4}{8}$

Entire length:  $8\frac{5}{8}$  Inches.

(2346) *EUPREPIS ERNESTII*, Dumeril and Bibron.

*Scincus ernestii*, Boie, MSS.

*Psammite de Van Ernest*, Cocteau.

*Dasia olivacea*, Gray: Catal.

Form like *E. rufescens*. Triangular incision of the palate very small, with a few minute pterygoid teeth on each side. Ears obliquely oval, small, appearing more so being half covered by two of the temporal scales; no lobules on the anterior margin. Scales of the back with minute longitudinally waved lines and from 3 to 8 indistinct keels. The outer half of the toes and the nails sharply compressed. A series of scuta beneath the tail.

*Very young*.—Head light green bronze, shields edged with black and a black line, edged with silver, from the muzzle to the ear. Back, sides, root of the tail and outside of the limbs shining black with numerous transversal, waved, silvery lines. Feet and toes rose, or flesh coloured. Tail brilliant scarlet. [Note. The very young of *Eumeces lessoni*. Dum, and Bibr, (*Scincus cyanurus*, Lesson,) is distinguished by a similar distribution of colours.] Throat, abdomen and inside of the limbs silvery white.

*Adult*—Ground colour greyish-brown bronze. Frontal and supraorbital shields black edged; fronto-parietals, inter-parietals, and parietals black, each with a whitish elongated mark, united, forming a symmetrical figure. From the nostril to the eye a black streak. Neck and body with a number (12 to 14) of distant, transversal, waved bands, composed of black scales, each with a rectangular white spot in the middle. Outside of limbs with 4 or 5 similar bands. In some a buff coloured lateral band on the posterior part of the back, and the anterior half of the side of the tail. Beneath iridescent light bluish-green; scales with whitish edges. Iris black with a golden narrow circle.

*Habit*.—*Malayan Peninsula, Pinang. Java.*

In habits this species resembles *Euprepes rufescens*, but appears to be far less numerous. In a female were found eleven eggs, in shape, size and colours resembling those of *E. rufescens*.

The young above described, was of the following dimensions:

Length of the head,.....  $0\frac{3}{8}$  Inch.  
Do do trunk,..... 1  
Do do tail,... ..  $1\frac{4}{8}$

Entire length...  $3\frac{1}{8}$  Inch.

Of the two adult individuals the large measured:

Length of the head,.....  $0\frac{6}{8}$  Inch.  
Do do trunk,.....  $3\frac{2}{8}$   
Do do tail,... ..  $4\frac{4}{8}$

Entire length...  $8\frac{4}{8}$  Inches.

*Sub-Gen. LYGOSOMA*, Gray, apud. Dum. and Bibr.

Nostrils pierced through the nasal shield; no supranasals; palate toothless, with a small triangular incision, situated far back; scales smooth.

Blindworm-like; limbs excessively small: tail strong, conical, about two-fifth of the entire length. A single large lozenge-shaped fronto-parietal shield. Ear minute, circular. Lower eyelid scaly, with a few larger scales. Pre-anal scales larger than the rest.

Ground colour; iridescent lighter or darker copper, or bronze, in some with indistinct dark brown zigzag lines, produced by the scales being laterally edged or dotted with that colour. Beneath pale or whitish yellow. The tail in some minutely dotted with brown. Iris black with a minute golden ring. The supraorbital scales

## REPTILES OF THE

being somewhat transparent, the black colour of the eye gives them a blackish appearance.

*Habit*.—*Pinang*. Singapore, Java.

But two individuals were observed in the Great Hill of *Pinang*, one by Sir W. Norris, the other by myself. The latter made its appearance through a hole in the soft, moist mould beneath a group of *Polycopodium horsfieldii*. Above ground its movements were very quick, serpent-like, apparently little assisted by the tiny limbs. The head of the larger measured  $\frac{2}{3}$  inch, the trunk  $2\frac{7}{8}$  inches in length. One had but 4 toes on the anterior feet. In both the tail was reproduced, which is also the case in a third, from Singapore, preserved in the Museum of the Asiatic Society.

### OPHIDIA.

#### INOCUOUS SERPENTS.

#### FAM. TYPHLOPIDÆ, GRAY.

#### BURROWING.

*Gen.* PILIDION, Dumeril and Bibron.

Head covered with shields, cylindrical, very short, as if truncated, convex above, declivous in front; muzzle rounded; rostral shield like a large rounded cap covering the head and muzzle; an anterior frontal, a frontal, a pair of supra-orbital, ocular, nasal, and fronto-nasal shields; neither parietals, inter-parietals, nor præ-orbitals; nostrils hemispherical, under the muzzle, between the nasal and fronto-nasal shields; eyes excessively small, hidden by the ocular shields.

(2348) PILIDION LINEATUM, (Boie.)

*Aconitas lineatus*, Reinwardt, M.S.

*Typholope lineatus*, H. Boie.

*Typhlina*, Wagler.

*Typhlops lineatus*, Gray in Griffith, A. K.

*Typhlops lineatus*, Schlegel.

*Pilidion lineatum*, Dumeril and Bibron.

*Typhlops lineatum*, Gray: Catal.

Ground-colour pale gamboge or orange, uniform on the head, the apical third of the tail, and the abdomen; interrupted on the back and sides by 12 longitudinal, serrated brown lines, produced by a minute triangular spot on each side of the scales.

*Habit*.—*Pinang Hills*. Java, Sumatra, Singapore.

A single individual, captured by Sir William Norris, differs from the description given by M. M. Dumeril and Bibron in the comparatively greater dimensions of the tail. It is strongly arched; its length equals twice the breadth of the head; it is covered with 16 transversal series of scales, and it is considerably thicker than the rest of the uniformly cylindrical body. The anterior frontal shield is very broad, larger than

the frontal. It was of the following dimensions:—

	Ft.	Inch.
Length of the head,.....	0	$0\frac{2}{3}$
Do. do. trunk,.....	1	$0\frac{7}{8}$
Do. do. tail,.....	0	$0\frac{2}{3}$

1 ft.  $1\frac{5}{8}$  inch.

Circumference of the trunk  $\frac{5}{8}$  inch, of the tail  $\frac{9}{8}$  inch.

*Gen.* TYPHLOPS, Schneider.

Head covered with shields, depressed; muzzle rounded, covered above and beneath by the rostral shield; an anterior frontal, a frontal, a pair of supra-orbitals, one or two pairs of parietals and inter-parietals; a pair of nasals, fronto-nasals, præ-orbitals and oculars; nostrils lateral, hemispherical, opening in the suture between the nasal and fronto-nasal; eyes lateral, more or less distinct; pupil round.

(2349) TYPHLOPS NIGRO-ALBUS, Dumeril and Bibron.

*SYN.*—*Argyrophis bicolor*, Gray: Catal.

Shining black above; on the head some transversal and radiating whitish yellow lines; scales of the back edged with white; beneath whitish yellow.

*Habit*.—*Pinang Hills*, Singapore. Sumatra.

This species is closely allied to *T. diardi*. Schlegel, [*SYN.*—*T. diardi*, apud Dum. and Bibr.—*Argyrophis horsfieldii*, Gray: Catal.] an inhabitant of Assam and the Khassia Hills. Of two individuals observed, the larger was of the following dimensions:

	Ft.	Inch.
Length of the head,.....	0	$0\frac{4}{5}$
Do. do. trunk,.....	1	0
Do. do. tail,.....	0	$0\frac{8}{8}$

1 ft.  $0\frac{7}{8}$  inch.

Circumference of the trunk  $\frac{7}{8}$  inch, of the tail  $1\frac{1}{8}$  inch.

(2350) TYPHLOPS BRAMINUS, (Daudin.)

*L'Orvet lombric*, Lacepede.

*Angvis*. Rondoo Talooloo Pam. Russell, l. Pl. 43.

*Punctulated Slow-Worm*; Shaw.

*Eryx braminus*, Daudin.

*Typhlops rondoo talooloo*, Cuvier.

*Tortrix russellii*, Merrem.

*Typhlops braminus*, apud { Cuvier.  
Fitzinger.  
Gray in Griffith  
A. K.

*Typhlops russellii*, Schlegel.

*Typhlops braminus*, Cuvier, apud Dumeril and Bibron.

*Argyrophis braminus*, Gray: Catal.

Shining copper-coloured, or brown of various shades above, paler beneath. Some individuals of a uniformly bluish white. All the scales with a dark brown spot at the anterior part. The shields of the head have a whitish line close to

their margins. In the young the latter is cre-nulated, and the sides of the head, lips, throat, the anal region, and the point of the tail are yellowish or whitish, and the body is semi-transparent.

*Habit* — *Pinang, Singapore, Malayan Peninsula.* Canton-Province, Philippines, Guam (Marian Isles), Java, Tenasserim, Bengal, Assam, Coromandel, Ceylon, Malabar.

In the Malayan countries this species is numerous in hills and valleys. The eyes are black, the pupil round, which is also the case in *T. nigro-albus*. The largest of a great number examined was of the following dimensions:—

	Inch.
Length of the head,.....	$0\frac{3}{8}$
Do do. trunk,.....	$7\frac{2}{8}$
Do. do. tail,.....	$0\frac{1}{8}$
	—
	$7\frac{6}{8}$ inch.

Circumference of the neck  $\frac{4}{8}$  inch; of the tail  $\frac{5}{8}$  inch.

The preceding species of this family are all of similar habits. They mostly live under ground, but appear occasionally in shady places, particularly after showers of rain, in Bengal, in the rainy season. They are very agile, and appear to make use of the horny point of the tail as a propeller. When taken, they frequently press it against the hand in their attempts to escape. Reposing on the ground *Typhlops braminus* may easily be mistaken for an earthworm, until its serpentine movements, the darting of the white furcated tongue, while the head and neck are raised, make it known. In confinement they refuse food and water. In all dissected, the stomach contained some earth; in a few, remains of insects, (myriapoda, ants.) A young female had a string of six cylindrical soft eggs, of a yellowish white colour, each about  $\frac{2}{8}$  of an inch in length,  $\frac{1}{16}$  in diameter.

FAM. BOIDÆ, BONAPARTE.

BURROWING.

*Gen.* CYLINDROPHIS, Wagler.

Scales smooth, imbricate hexagonal; those of the abdomen broader than the rest; nostrils sub-vertical, opening in the lower part of the anterior frontal shield; neither nasals, frenals nor præ-orbitals; a single post-orbital; frontals large, reaching the minute eye, and the large 2nd and 3rd labials; supra-orbitals, occipitals and vertical distinct; tail very short.

*Scytale scheuchzeri*, Merrem.

*Ilysia rufa* Lichtenstein, apud Fitzinger.

*Cylindrophis resplendens*, Wagler.

*Cylindrophis rufa*, Gray, apud Dumeril and Bibron.

Iridescent blackish brown above, beneath with alternate black and yellowish white transversal bands or interrupted bars. Iris black, pupil vertically contracted by the light, tongue whitish. Central series of abdominal scales 206; sub-caudal 6.

*Habit.*—*Singapore.* Java, Tranquebar, Bengal. (?)

A single individual, turned up with the earth, in a garden at Singapore belonging to Dr. Montgomerie, differs from the description given by M. M. Dumeril and Bibron in the following particulars. The head is uniformly black, without the two scarlet frontal spots; the apex of the tail whitish; the posterior part of the body is more robust than the anterior; the length of the head forms more than  $\frac{1}{8}$  of the entire length of the animal; there are six pairs of labial shields on each jaw, and the scales of the trunk are disposed in 20 longitudinal series. It unites characters assigned by M. M. Dumeril and Bibron as distinguishing *Cylindrophis rufus* from *C. melanotus*, Wagler, and it would therefore appear that Dr. Schlegel is justified in considering the latter from Celebes (*Tortrix melanota*, Boie, M.S.) as a variety of *rufa*. In the present individual there is no external appearance of the very rudimentary anal hooks. It was slow in its movements, attempted to escape, but not to bite.

	Ft.	Inch.
Length of the head,....	0	$0\frac{3}{8}$
Do. do. trunk,..	1	$6\frac{2}{8}$
Do. do. tail,....	0	$0\frac{3}{8}$

1 ft.  $7\frac{1}{8}$  inch.

*Gen.* XENOPELTIS, Reinwardt.

Head rather narrower than the trunk, depressed, obsoletely angular; eyes small, round; nostrils large, apical; frenal shield very large; præ-orbital none; [Note. The single præ-orbital is very large, the frenal small, sub-rectangular; the nostrils open between the latter and the nasal shield], post-orbitals three; [Note. Three individuals examined, presented two post-orbital] interparietal very large, equalling the vertical; trunk thick, short with imbricate smooth hexagonal scales, disposed in longitudinal series, increasing in size towards the narrow abdominal scuta; tail thick, short, awl-shaped, beneath with scutella.

# REPTILES OF THE

(2352) *XENOPELTIS UNICOLOR*, Reinwardt.

*Xenopeltis unicolor*, Reinwardt (young.)

Guerin: Iconog. Pl. 21, Fig. 3.

*Tortrix xenopeltis*, Schlegel.

*Adult*.—Blackish or reddish brown above with strong metallic blue, purple, and green lustre; lips and throat buff; the lowest lateral series of scales, scuta and scutella pale reddish brown with broad whitish margins. Iris black; pupil lanceolate with the apex downwards, vertically contracted by the light: tongue buff.

*Young*.—Head yellowish white with a brown spot on the crown and labial shields; the scales of the sides edged with white, producing longitudinal zigzag lines; the two lowest series of scales and scuta yellowish white; scutella of the same colour with a brown transversal line.

Scuta 175 to 179; Scutella 26 to 27.

*Habit*.—*Penang, Singapore, Malayan Peninsula, Celebes, Java Sumatra.*

Of three young individuals, one was found by Sir William Norris on the Great Hill at Penang, a second by Dr. Montgomerie at Singapore, and a third was obtained in Province Wellesley, where also a single adult male was killed. As this serpent in general appearance bears a strong resemblance to *Lycodon aulicus*, (Linne) [Syn. *L. hebe*, apud Schlegel], so it also does in its fierce habits, and mode of attack. The scales are smooth, rhombic-hexagonal, disposed in 15 longitudinal series. Labial shields  $\frac{8}{8}$   $\frac{8}{8}$ . The stomach of a young individual examined, contained the remains of a rat. The adult attains to a much larger size than supposed: a male was of the following dimensions.—

	Feet.	Inch.
Length of the head, . . . . .	0	$1\frac{4}{8}$
Do. do. trunk, . . . . .	3	$2\frac{3}{8}$
Do. do. tail, . . . . .	0	4

3 ft.  $7\frac{7}{8}$  in.

Circumference of the neck  $2\frac{6}{8}$ , of the trunk  $4\frac{2}{8}$ , of the root of the tail 2 inch.

## TERRESTRIAL.

*Gen. PYTHON*, Daudin.

Entire shields under the abdomen and tail, the latter cylindrical, sometimes with scutella; anus with scales and a hook on each side.

*Constrictor* (*P. schneideri*, Kuhl) Wagler.

*Python reticulatus*, Gray, apud Dumeril and Bibron.

"*Ular sawa*" of the Malays.

[\* Note. *Python javanicus*, figured and described in Abel's Narrative, &c., is *Python molurus*, (Linne.)]

Ground-colour above light yellowish-brown, chestnut or olive-green, assuming a greyish hue on the sides, all the colours strongly iridescent, particularly reflecting metallic blue, or green. The head is divided from the muzzle to the nape of the neck by a black line, continued along the back to the point of the tail and describing a series of large lozenges, sometimes linked to each other by a small blacking, sometimes broken up into large irregular patches. A black oblique line proceeds from behind the eye towards the angle of the mouth, continuing on the sides as a series of more or less regular lozenges, which are joined to the lateral angles of those of the back by a large black triangular spot with a white arched mark in the centre. The scales nearest the black margins of the lozenges are of a lighter colour than the rest, sometimes whitish. Between and within the lateral lozenges appear numerous black spots, or interrupted lines. The lips (the lower in some present a black line), and abdominal scuta are gamboge, or pale yellow, as well as the lowest two or three series of scales, but the latter with irregular black spots. The caudal scutella, and scuta, when present, are yellow, marbled with black. The iris is silvery flesh-coloured or yellowish-brown, sometimes with a black bar; the pupil vertically contracted by the light. The tongue is black above, bluish white beneath. In the young the colours are brighter than in the adult.

Scuta 297 to 330. Scutella 82 to 102.

*Habit*.—*Malayan Penang and Islands. Chusan? Amboina, Java, Banka, Sumatra, Bengal?*

[Note. Skins are of frequent occurrence at Chusan, and the natives assert that the serpent is found there and on the neighbouring continent. Serpents from 14 to 16 feet in length, "Rock-snakes," were observed by several officers during our occupation of the island.

M.M. Dumeril and Bibron state that this species has been sent from Bengal by M. A. Duvaucel. The natives are not acquainted with it and the specimens in the Museum of the Asiatic Society are from Penang. The living animal is occasionally brought from the Straits of Malacca to Calcutta, and such is probably the

# MALAYAN PENINSULA AND ISLANDS.

history of the specimen sent from Bengal by M. Duvaucel. *Python molurus*, (Linne,) [Pedda Poda and Bora of Russell,] is very numerous in Bengal.

The two fossets of the rostral shield are pyriform with the apex diverging, and those of the nearest 3 or 4 upper labials are of similar shape. The inferior fossets are square, occupying the lower margin of the shield, varying from 7 to 9 on each side. The foremost of these is situated on the shield corresponding to that of the upper jaw, which borders the orbit.

This species is very numerous in the Malayan hills, and valleys, feeding upon quadrupeds and birds. It often takes up its abode in out-houses, preying at night, and is thus useful in destroying vermin, although plunder is occasionally committed in poultry yards. Dr. Montgomerie has seen in George Town, Penang, a young one which the inhabitants suffered to retain unmolested possession of the rice stores in order to secure them against the ravages of rats. Individuals of 16 ft. in length are of no rare occurrence. In 1844 one was killed at the foot of Penang, which a gentleman informed me measured more than 30 ft. During the expedition to China in 1840 one was shot from the poop of one of H. M. Transports, then riding in Singapore roads, between 3 and 4 miles from the shore. It was about 9 ft. long, and had the upper part of the head infested with *Ixodes ophiophilus*, Muller. The Chinese attribute great medicinal qualities to the heart and the gall bladder, and use the skin to cover the bodies of some of their musical instruments. *Python molurus*, (Linne,) Pedda Poda, Russell, I. Pl. 22, 23, 24, and Bora, Pl. 39, is said to occur, but rarely, in the Malayan Peninsula, but I never had an opportunity of seeing it.

## AQUATIC.

*Gen.. ACROCHORDUS*, apud Schlegel.

(*Acrochordus*, Hornstedt, 1787.—*Chersydrus*, Cuvier, 1817.)

*Acrochordus*, Hornstedt. Nostrils vertical, eyes encircled by a ring of minute scales; trunk compressed, attenuated towards both extremities; tail tapering, compressed; all the scales small, trifid, strongly keeled.

(2354) *ACROCHORDUS JAVANICUS*, Hornstedt.

*Acrochordus javanicus*, apud Shaw.

*Acrochordus javensis*, Lacep. apud Cuvier.

*Acrochordus javanicus*, apud Schlegel.

"Ular karong, or sapi, or lembu" of the Malays.

[Note. Ular signifies a serpent, karong a sac; sapi and lembua cow or ox. These expressive vernacular names refer to the loose skin, and the bulk of the animal.]

*Young.* Above dull greyish-brown; sides and lower parts pale yellow, or dirty ochre;

back with 3 longitudinal, undulating, frequently interrupted black bands; sides and abdomen with rows of rounded spots, marbled and dotted with black.

*Adult.* Of similar, but less distinct colours. Iris brown, pupil elliptic, vertically contracted by the light; tongue whitish.

*Habit.*—*Pinang, Singapore.* Java.

A female captured on the Great Hill at Pinang, at a distance from water, was of the following dimensions:

	Ft.	inch.
Length of the head,.....	0	1 $\frac{1}{8}$
Do. do. trunk,.....	1	7
Do. do. tail,....	0	9
		5 ft. 5 $\frac{1}{8}$ inch.

Greatest circumference one foot.

Notwithstanding the sharply compressed abdomen, the serpent moved without difficulty, but sluggishly on the ground, and preferred quiet. When touched she attempted to bite, but the pupil being contracted by the glare, she missed her aim. Shortly after being brought, while the rest of the body remained motionless, the posterior ribs were observed moving, and the serpent successively, in the course of about 25 minutes, brought forth twenty-seven young ones. Each birth was followed by some sanguinolent serum. With two exceptions the foetus appeared with the head foremost. They were very active, bit fiercely, and their teeth were fully developed. Shortly after birth the integuments came off in large pieces, which is also the case with the foetus of several species of *Homalopsis*. The present ones were placed in water, which however appeared to distress them, as they all attempted to escape on dry ground. Nearly all were of the following dimensions:—

	Ft.	Inch.
Length of the head,.....	0	0 $\frac{5}{8}$
Do. do. trunk,.....	1	1 $\frac{3}{8}$
Do. do. tail,.....	0	3
		1 ft. 5 inch.

The Malays of Pinang assert that this species is of very rare occurrence. During a residence of 20 years at Singapore, Dr. Montgomerie observed it but in a solitary instance. The physiognomy of this species bears a striking resemblance to that of a thorough-bred Bull dog, which in a somewhat less degree also may be said of the following.

*Sub-Gen. Chersydrus.* [This Sub-Gen. was founded upon the erroneous supposition that *Acrochordus fasciatus*, Shaw, possessed venomous organs.] Cuvier. Head and body uniformly covered small scales.

(2355) *ACROCHORDUS GRANULATUS*, (Schneider.

*Hydrus granulatus*, Schneider.

*Anguis granulatus*, Schneider.

# REPTILES OF THE

*Acrochordus fasciatus*, Shaw.  
*Acrochordus dubius*, Shaw.  
*Pelamis granulatus*, Daudin.  
*Chersydrus* (*A. fasciatus*, Shaw), Cuvier.  
*Acrochordus fasciatus*, apud Raffles.  
*Chersydrus granulatus*, Merrem, apud Wagler.  
*Acrochordus fasciatus*, apud Schlegel.  
 "Ular limpa," or "Ular laut" of the Malays.

Limpa, i. e. liver, liver-coloured.

**Young.** Blackish-brown or liver-coloured; the head with a few scattered yellowish white spots, the rest of the body with numerous rings of the latter colour, some interrupted on the back, others on the abdomen.

**Adult.** The dark colours fade to a dull greyish black, uniform on the back, and the sides and abdomen present alternate dark and whitish vertical bands. Iris black, pupil vertically contracted; tongue whitish.

**Habit.**—*Rivers and sea-coast of the Malayan Peninsula and Islands.* Bay of Manila, New-Guinea, Timor, Java, Sumatra, Coromandel.

This species appears not to exceed about 3 ft. in length. The body is less bulky and the skin less loose than in *A. javanicus*. But the form is more compressed, particularly the sword, or oar-like tail, and like that of the pelagic venomous serpents, appear exclusively calculated to aquatic habits. The scales also resemble those of the latter, and are generally smaller than in *A. javanicus*. Those of the back, the largest, are rounded rhombic, each with a minute tubercle in the centre. The skin in the interstices is finely wrinkled. On the abdomen the scales are mucronate, with a sharp, reclining central point. In both species the medial line is raised by 2 or 3 quincunx rows of scales with their points overlapping each other. The orbit is surrounded by a ring of scales a little larger than the rest. The nostrils, pierced high up on the muzzle, are almost vertical, slightly more so than they are in *A. javanicus*. In both they are tubular, larger in the present species, sinuous, and provided with a deeply seated membranous fold, which can hermetically close the passage. The mouth is secured in a similar manner by a central arched notch and two lateral protuberances, which correspond to a protuberance and two lateral cavities in the lower jaw. This contrivance also occurs in *Hydrus*, and to a certain extent in *Homalopsis*. With the exception of the dentition and the absence of venomous organs, in anatomical details both species of *Acrochordus* closely resemble *Hydrus*. As observed by M. Schlegel, the most striking feature is the great development of the lung, which occupies nearly three-fourths of the extent of the abdominal cavity. A somewhat similar arrangement also occurs in *Homalopsis*. All the maxillary teeth (inter-maxillary none) are strong, pointed, inwardly reclining and disposed in double or

treble rows. The 3 anterior teeth are the shortest: the upper jaw has on each side upwards of 20 teeth, the lower 3 or 4 less. The palatal teeth number 12 on each side, the pterygoid 9, and are shorter than the rest. *Acrochordus granulatus* is of no rare occurrence in the sea of the Malayan coasts although, according to Raffles, it is rarely seen on the coasts of Sumatra. At Pinang they are found among the fishes, taken in the stakes some 3 or 4 miles distant from the coast. M. Schlegel is mistaken in stating that this species never inhabits the sea, [Note. Essai, &c. p. 492.] and in censuring M. Eschscholtz, for his stating that the fishermen often take it in the Bay of Manila. A female of the following dimensions had six eggs:—

	Feet.	Inch.
Length of the head,.....	0	0 $\frac{5}{8}$
Do. do. trunk,.....	2	7 $\frac{3}{8}$
Do. do. tail,.....	0	3 $\frac{5}{8}$

2 ft. 11 $\frac{1}{8}$  inch.

Greatest circumference, 4 inches.

The egg is cylindrical, soft, coriaceous, whitish, about 1 $\frac{1}{2}$  inch in length. In each egg was coiled up a living young one of the following dimensions:

	Inch.
Length of the head,.....	0 $\frac{3}{8}$
Do. do. trunk,.....	9
Do. do. tail,.....	1 $\frac{4}{8}$
	10 $\frac{7}{8}$ Inch.

Greatest circumference, 1 inch.

In food and general habits, this species resembles the pelagic, venomous, serpents; in its element, it is active, but on dry land, blinded by the daylight, it is sluggish and of uncertain movements.

## FAM. COLUBRIDÆ, BONAPARTE. TERRESTRIAL.

*Gen. CALAMARIA*, H. Boie.

Body diminutive, elongated, obtuse at both extremities, throughout of equal diameter, cylindrical; eyes very small with round pupil; frontals one pair, laterally extending to the labials; frenals none; nostrils lateral, opening in a small shield between the frontal, rostral and anterior labial; one præ-orbital, four mental shields; dorsal scales rhombic, polished, smooth; tail very short.

(2356) *CALAMARIA LUMBRICOIDEA*, Schlegel, Var.

*Calamaria lumbricoidea*, Boie, MS.

*Calamaria virgulata*, Boie MS. (Young.)

Strongly iridescent, brownish-black, lighter, on the head scales with whitish edges; cheeks, lips and throat citrine; the lowest row of scales and abdominal surface yellowish white; sub-caudal scutella faintly marked with brown; eyes and tongue black.

# MALAYAN PENINSULA AND ISLANDS.

Scuta 169; Scutella 26.

*Habit.*—*Pinang, Singapore. Celebes, Java.*

This variety differs in nothing but colours from the species described by M. Schlegel. Of three individuals observed, two were taken by Sir W. Norris and W. T. Lewis, Esq. in the hills of Pinang, the third by Dr. Montgomerie at Singapore. The largest was of the following dimensions:

	Inch.
Length of the head,.....	$3\frac{3}{8}$
Ditto. ditto. trunk,.....	$11\frac{6}{8}$
Ditto. ditto. tail,.....	$1\frac{3}{8}$
	1 ft. $1\frac{4}{8}$ inch.

Circumference  $\frac{9}{8}$  inch.

The livery bears a remarkable resemblance to that of *Calamaria alba* (Linne), (*C. brachyorrhos*, Schlegel,) from which it however differs in the absence of the anterior frontal shields, and in having 13 instead of 17 longitudinal series of scales.

(2357) *CALAMARIA LINNEI*, H. Boie, Var. Schlegel.

*Calamaria reticulata*, Boie. MS. ?

*Changulia albiventer*, Gray: Ill. Ind.

Zool. Pl.—Fig. 6.9.\*

*Calamaria linnei*, Var. Schlegel.

[\* Note. Referred by M. Schlegel to *C. lumbricoidea*, but the characteristic distribution of the colours is that of the present Var. The figure however is not good, and not coloured from life.]

*Adult.*—Head brown, minutely dotted with black, lips and cheeks pale gamboge; trunk reddish brown, on each side with two vermillion longitudinal bands with black serrated edges; beneath carmine, with a black serrated line on each side; subcaudal scutella with a central black, zig-zag line; all the colours strongly iridescent; eyes black, tongue vermillion.

*Young.*—Like the adult, but with a broad black nuchal band, edged with white, a vermillion band at the root of the tail, and in some a similar near the point.

Scuta 166; Scutella 17.

*Habit.*—*Penang, Java.*

The present variety corresponds in all particulars to the description of *C. linnei* by M. Schlegel, who however does not mention that the two or three anterior teeth on each side of the lower jaw are longer than the rest. Of six individuals from the hills of Penang the largest individual measured—

	Inch.
Length of the head,.....	$0\frac{2}{8}$
Do. do. trunk,.....	$10\frac{1}{8}$
Do. do. tail,.....	$0\frac{5}{8}$
	11 Inch.

Circumference of the neck  $\frac{3}{8}$ , of the trunk  $\frac{4}{8}$  inch.

(2358) *CALAMARIA LONGICEPS*. n. s.

Strongly iridescent soot-coloured, a shade, lighter beneath; the scuta and scutella edged with whitish. Eyes and tongue black.

Scuta 131; Scutella 26.

*Habit.*—*Pinang.*

The head is elongated, narrow, conical; the muzzle rounded, projecting over the lower jaw. The anterior frontals are much smaller than the frontals, which on the sides occupy the place of the absent frenal shield, and thus reach the second upper labial; the nasal is very small, rectangular, perforated by the rather large nostril near the lower anterior angle. The eye is comparatively large, between an obliquely placed rectangular præ-orbital, and a similar post-orbital shield; the supra-orbitals are narrow, rectangular; the vertical moderate, pentagonal, arched and somewhat narrowed at the anterior margin. The occipitals, the largest, are elongated, bordered below by the large fifth upper labial, and behind by a single pair of post-occipitals. Each jaw has 5 pairs of labials. Of the 2 pairs of mentals, the anterior is the longer, and is enclosed by the rostral and 3 anterior labials, the posterior pair, by the fourth labial. The teeth are minute, sharp, reclining, all of equal size. The trunk is cylindrical, narrowed towards both extremities, covered with 15 longitudinal series of smooth, rhombic, imbricate scales. The abdomen is arched, the short tail tapering to a blunt point. This species approaches to *Calamaria alba* (Linne), (*C. brachyorrhos*, Schlegel,) but differs by its elongated shape of the shield of the head, and its larger eyes. A single individual, captured by W. T. Lewis, Esq., on the Great Hill of Pinang, was of the following dimensions:

	Inch.
Length of the head,.....	$0\frac{3}{8}$
Do. do. trunk, .....	5
Do. do. tail, .....	$0\frac{6}{8}$
	$6\frac{1}{8}$ inch.

Circumference of the trunk  $\frac{9}{8}$ , of the neck  $\frac{3}{8}$ , at the root of the tail  $\frac{3}{8}$  inch.

(2359) *CALAMARIA SAGITTARIA*.

*Calamaria sagittaria*, Cantor: Spicil.

Head yellow or white, marbled with black, forming a streak above the citrine lips; neck white with a black arrow-shaped mark; back partly ash, partly rust-coloured, with a medial series of distant minute black spots; sides bluish-black or grey, with a narrow black line above; beneath citrine, the throat marbled with black, and with a minute black spot near the lateral angle of each scutum. Iris golden; tongue carmine.

Scuta 216 to 227; Scutella 57 to 70.

*Habit.*—*Malayan Peninsula. Bengal, Assam.*

But for the diminutive size, and the reduced shields of the head and throat, this species

## REPTILES OF THE

might be taken for a *Coronella*. The head is but little distinct, depressed, ovate, covered by the normal number of shields. The anterior frontals are very small, pentagonal; the frenal short rectangular. The nostrils are rather large, piercing the middle of the nasal. The eyes are large, prominent with one præ-orbital, two post-orbitals; the upper jaw, but slightly longer than the lower, has on each side 6 labials, the lower 7, enclosing two pairs of small mentals. The temples are covered by three shields. The trunk, with 17 longitudinal series of smooth, rhomboidal imbricate scales, is slightly thicker towards the middle than at the extremities; the back throughout depressed, forming an angle with the sides, and the abdomen is flat, which makes a vertical section of the body square. The tail is very slender, tapering to a sharp point, and exceeds one-fifth of the entire length. The teeth are very minute, of equal size. A single specimen from the Malayan Peninsula was of the following dimensions:

	Inch.
Length of the head,.....	$0\frac{3}{8}$
Do do. trunk,.....	$9\frac{5}{8}$
Do. do. tail,.....	$2\frac{2}{8}$
	<hr/>
	$11\frac{7}{8}$ Inch.

Circumference of the trunk  $\frac{4}{8}$ : of the neck and root of the tail  $\frac{3}{8}$  inch.

In Bengal this species is of no uncommon occurrence particularly during the rainy season, when the water compels the serpents to leave the shady recesses which most of them occupy to avoid the heat of the day. The present species appears to be closely allied to the African *C. arctiventris*, Schlegel.

Of the preceding four species, the three first appear at Penang exclusively to inhabit the hills, but the variety of *C. lumbricoidea* occurs at Singapore in valleys. They are nowhere to be met in numbers. They are of gentle peaceable habits, never attempting to bite, and scarcely to escape. They are sluggish, move but slowly, and to a short distance, even when compelled by danger, and soon resume the motionless position which they appear to affect. The remarkable abstinence of most of their congeners, they possess but in a very limited degree. In captivity they refuse food, and soon expire; besides, they are so delicate, that slight pressure in examining them, is sufficient to kill them. Their bodies are very smooth, and brilliantly reflect rainbow-colours, which continue in preserved specimens, long after the gay livery has faded. They feed upon slugs, earth-worms, and insects.

The stomach of a *C. sagittaria* contained remains of an *Iulus* and some sand. In general appearance and habits these species of *Calamaria*

*Gen. CORONELLA*, Laurenti.

Head above covered with large plates, of which one between the eyes; sides of the head and occiput with imbricate scales; trunk narrowed near the head, thicker towards the middle; tail conical, elongated, tapering to a sharp point.

(2360) *CORONELLA BALIODEIRA*, Schlegel.

Patza Tutta, Russell I. Pl. 29?

*Coluber pictus*, Daudin?

*Coluber plinii* Merrem?

*Coronella baliodeira*, Boie. M.S.

Above slighter or darker olive brown, yellowish on the head, the scales minutely dotted with dark brown; the anterior part of the trunk with a number of distant transversal ocellated lines, composed of single transversal series of white scales, edged with black, labial shields yellow edged with black; beneath pearl coloured or yellowish white; iris golden, lower half blackish; tongue black.

Scuta 122 to 132; Scutella 65 to 72.

*Habit.*—Pinang. Java.

Of two individuals from the hills of Pinang, the larger was of the following dimensions:

	Ft.	Inch.
Length of the head,.....	0	$0\frac{5}{8}$
Do. do. trunk,.....	0	$8\frac{5}{8}$
Do. do. tail,.....	0	$3\frac{5}{8}$
	<hr/>	<hr/>
	1 ft.	1 inch.

Circumference of the neck  $\frac{4}{8}$ , of the trunk  $\frac{7}{8}$ , of the root of the tail  $\frac{3}{8}$  inch.

Both agree with the description of *M. Schlegel*, except in having two small præ-orbitals instead of one. Russell's No. 29, from Casemcottah, which according to *M. Schlegel* is *Coluber pictus*, Daudin, *C. plinii*, Merrem, is probably intended to represent the present species. It is of fierce habits.

*Gen. XENODON*, H. Boie.

Head scarcely distinct, muzzle obtuse, nostrils rounded, between 3 shields; eyes encircled behind only by 3 shields; trunk short robust; tail rather short, slowly tapering; 4 very large mentals, the last upper maxillary tooth the longest.

(2361) *XENODON PURPURASCENS*, Schlegel.

*Coronella albocincta*, Cantor. (Var.)

Above olive brown with black spots, and numerous pale red transversal zig-zag bands, each with a submarginal black line. The first occupies the space between the eyes, continuing obliquely backward over the cheeks and lips; the second, arrow-shaped, diverging over the neck; labial shields yellow with brown margins. Beneath strongly iridescent pale carmine; every other scutum entirely or partially black near the lateral angles. Iris circular, golden, lower half dotted with black; tongue black.

Scuta 179 to 183; Scutella 36 to 65.

*Habit.*—Penang. Java, Tenasserim, (Var.) Chirra-Punji, Assam, Darjeeling, Midnapore (Ben-

# MALAYAN PENINSULA AND ISLANDS.

A solitary individual observed on the summit of the Great Hill of Pinang, defended itself vigorously. The dimensions were :

	Ft.	Inch.
Length* of the head,.....	0	1
Do. do. trunk.....	1	8 $\frac{3}{8}$
Do. do. tail.....	0	3 $\frac{5}{8}$
	2 ft.	1 in.

Circumference of the neck,  $1\frac{1}{8}$  of the trunk 2, of the root of the tail  $1\frac{1}{8}$  inch. It differs from the description of M. Schlegel in having 21 longitudinal series of scales instead of 19, and on the right side 3 præ-orbitals. Labials on each side  $\frac{8}{10}$ . The variety described as *Coronella albocincta* inhabits Assam, Chirra Punji, Darjeling, Midnapore (Bengal.) It differs from those of the southern localities in having the head not distinct from the trunk, and its shields are shorter. The eyes are smaller, and, owing to the much swollen cheeks, appear sunk, which with the remarkably shelving profile, contribute to render the physiognomy singularly scowling. The largest specimen in the museum of the Asiatic Society measures in length 2 feet  $5\frac{3}{8}$  inch, of which the head  $\frac{6}{8}$ , the trunk 2 feet  $1\frac{5}{8}$ , and the tail 3 inch. In all, the livery is individually varying, but the arrow-shaped mark, double in some, appears to be constant. Labials on each side  $\frac{7}{9}$ .

Gen. LYCODON, H. Boie.

Head not very distinct, oblong, depressed ; supra-orbital shield triangular narrow in front ; præ-orbital one ; post-orbitals two ; frenal one ; eyes sunk, far removed from the muzzle ; pupil vertical ; trunk elongated, somewhat compressed with smooth, rhomboidal, imbricate scales ; tail short, tapering ; anterior maxillary teeth longer than the rest. \*

(2362) LYCODON AULICUS, (Linne)

*Coluber aulicus*, Linne (not apud Daudin.)

Russell \* I. Pl. 16, Gajoo Tutta.

*Coluber striatus*, Shaw.?

*Coluber malignus* Daudin.

*Lycodon hebe*, Boie, apud Wagler, Schlegel (excl. synonym. *Col. hebe*, Daud.)

[\* Note. Russell 1, Pl. Karetta upon which is founded *Coluber galathea*, Daudin, appears to represent the present species, or one of its varieties.

[Note by Mr. Elliot—There are numerous varieties of *Lycodon aulicus*, I have met with several more than are enumerated here.]

Lighter or darker chestnut with numerous white transversal bands, (in some spotted with black,) on the sides forming a forked network, composed of brown scales edged with white ; on each side of the hindhead a white triangular spot (confluent in some,) with brown spots, lips similarly coloured ; beneath pearl-coloured ; eyes black ; tongue whitish.

Habit.—*Pinaug*. Bengal, Coromandel.

Var. A.

*Lycodon hebe*, Var. Schlegel.

With a number of large square white spots, with black edges and central spots.

Habit—*Pinang*. Bengal.

Var. B.

Russell II, Pl. 37.

*Lycodon capucinus*, Boie.

*Lycodon hebe* Var. *javan*, Schlegel.

*Lycodon atropurpureus*, Cantor.

Chestnut or deep purple marbled with white veins, edged with black, with or without a white collar.

Habit.—*Pinang*, *Malayan Peninsula*. Tenasserim Provinces, Java.

Var. C.

*Lycodon hebe*, Var. *timorensis*, Schlegel.

Chestnut, with a white collar, and indistinct traces of white network.

Habit.—*Pinang*, *Malayan Peninsula*, Pulo Samao, Timor.

Var. D.

Russell II, Pl. 39.

*Lydocon subfuscus*, Cantor.

Uniformly light brown above, the lips white, edged with brown.

Habit.—*Malayan Peninsula*. Bengal.

This species occurs in the Malayan countries, both in the hills and valleys, but it is apparently not so numerous as it is in Bengal. It is of fierce habits and defends itself vigorously. In one examined the stomach contained a young *Euprepis rufescens*, (Shaw).

The largest individual observed, Var. B., was of the following dimensions :—

	Feet.	Inch.
Length of the head,.....	0	0 $\frac{2}{8}$
Do. do. trunk,.....	1	8 $\frac{7}{8}$
Do. do. tail,.....	0	4 $\frac{1}{8}$
	2 ft.	1 $\frac{5}{8}$ in.

Circumference of the neck 1 inch, of the trunk  $1\frac{1}{8}$ , of the root of the tail  $\frac{7}{8}$  inch.

*Ophites*, Wagler, differing from *Lycodon*, in the absence of the præ-orbital shield ; frenal elongated ; eyes small, scales rhombic with truncated points ; some of the posterior dorsal scales keeled.

(2363) LYCODON PLATURINUS, (Shaw.)

Seba Thes I, 83, 3.

Russel, II, Pl. 41.

*Coluber platurinus*, Shaw.

*Coluber platyrhinus*, Merrem.

*Lycodon subcinctus*, H. Boie.

*Ophites*, Wagler.

*Lycodon subcinctus*, apud Schlegel.

Shining blackish brown with steel blue reflec-

## REPTILES OF THE

bands, the lips, throat and a collar all white, spotted with black; beneath pale blackish brown, the anterior part of the abdomen, the sharp lateral angle and the broad posterior margins of the scuta and scutella whitish. Eyes black; tongue flesh-coloured.

Scuta 221; Scutella 74.

*Habits.*—*Penang*. Java, Bengal.

[Note. According to M. Schlegel, who observes that a specimen has been forwarded from Bengal by M. Duvaucel. No specimen exists in the Museum of the Asiatic Society, nor are the natives acquainted with the species.]

On both sides of each jaw the anterior 4 or 5 teeth increase in size and are longer than the rest. The fifth upper maxillary tooth is removed from the preceding, which in addition to the general shape of the head and the lax integuments, imparts to this serpent a striking resemblance to the venomous genus *Bungarus*. In fierceness it resembles the preceding species. The only individual observed was captured near the summit of the Great Hill of Pinang, where it had seized a large *Euprepis rufescens*, (Shaw.) It was of the following dimensions:

	Feet.	Inch.
Length of the head,.....	0	1
Do. do. trunk,.....	2	$8\frac{4}{8}$
Do. do. tail,.....	0	$7\frac{4}{8}$
	3 ft.	5 in.

Circumference of the neck  $1\frac{5}{8}$ , of the trunk  $2\frac{4}{8}$  inch.

(2364) *LYCODON EFFRÆNIS*, n. s.

Shining bluish black above, with a few minute white spots, not affecting the ground colour; the throat, lips, and a band bordering the sides of the head from the muzzle to the hind head, buff coloured, finely marbled with black; beneath strongly iridescent, pale bluish black, the scuta with whitish edges; the body encircled by a number (11,) of broad distant buff rings, above with indentated margins. Eyes black, pupil elliptical; tongue whitish.

Scuta 228; Scutella 72.

*Habit.*—*Pinang*.

The head is elongated, ovate depressed, broader than the neck, the muzzle rounded, slightly projecting; the anterior frontals are orbicular pentagonal, much smaller than the frontals which are bent over the sides, substituting the absent frenal, so as to meet the second upper labial; the nasal is small, rectangular, obliquely wedged in between the rostral, the two pairs of frontals, and the anterior upper labial; the nostril large, piercing the middle of the shield; the vertical is elongated pentagonal, broader in front, so as to render the posterior part of the moderate supraorbitals broader than the anterior;

each side surrounded by 3 scales, somewhat longer than the rest covering the temples, and behind by two small post occipitals. The eyes are proportionally large and prominent, surrounded by one præ-orbital and two smaller post-orbitals, the lower of which touches the narrow projecting fifth upper labial, which with the fourth, borders the lower part of the orbit; the jaws are covered by 8 pairs of upper, 9 of lower labials. The gape is moderate; the particulars of the dentition noted in *L. platurinus*, exist in the present species. The two anterior of the three pairs of small elongated mental shields are bordered by the six anterior pairs of labials; behind by a number of small scales. The trunk is slender, decreasing towards both extremities, with 17 longitudinal series of smooth, rhomboidal, slightly imbricate scales. The back is depressed, forming an angle with the compressed, somewhat bulging sides. The latter are joined to the flat narrow abdomen under a right angle on the sides of the scuta, so that the vertical section of the body is quadrangular. A single individual found by Sir Wm. Norris on the Great Hill of Pinang, was of the following dimensions:

	Ft.	Inch.
Length of the head,.....	0	$0\frac{4}{8}$
Do: do. trunk,.....	0	$9\frac{4}{8}$
Do. do. tail,.....	0	$2\frac{2}{8}$
	1 ft.	$0\frac{4}{8}$ inch.

Circumference of the neck,  $\frac{4}{8}$ , of the trunk  $\frac{5}{8}$ , of the root of the tail  $\frac{2}{8}$  inch.

In fierceness the present species resembles its congeners, but unlike them, it raises vertically the anterior part of the body, and bites after a few oscillating movements from side to side. *Lycodon platurinus*, and *auicus*, like many other harmless, and some venomous serpents, the pupils of which are vertically closed by the light, prepare to attack horizontally coiled on the ground, with the head bent close to the body, and drawn as far backwards as possible, when, suddenly uncoiling the anterior part of the body, they dart obliquely upwards, but as they are blinded, not always in the direction apparently aimed at, and they frequently miss the aim.

*Gen.* COLUBER, Linne.

Abdomen with scuta; scutella under the tail.

(2365) *COLUBER FASCIOLATUS*, Shaw.

Russell, I. Pl. 21 Nooni Paragoodoo.

*Coluber hebe*, Daudin (Synon, apud Boie, Wagler, Schlegel).

“Cinereous grey with an obscure cast of reddish brown, particularly about the head and neck. The back variegated by black and white, or black and yellowish, narrow bands; and on the sides are two or three rows of short, separate

## MALAYAN PENINSULA AND ISLANDS.

of the lateral scales; but in general these bands are not visible on the tail. The scuta (192) and scutella (62) are of a dusky pearl-colour." (Russell I. pg. 26.)

*Habit.*—*Malayan Peninsula.* Coromandel Coast.

A young individual, killed in Province Wellesley corresponds to the description of Russell, copied by Shaw and Daudin. It has too small post-orbitals, one elongated pre-orbital, one minute irregularly hexagonal frenal, and on each side 8 upper, 9 lower labial shields. The trunk is covered by 21 longitudinal series of smooth imbricate scales, which are rhombic on the sides, rhomboidal above, all with rounded points. The teeth are of uniform size, and as Russell correctly describes them, very small, reflex, sharp, numerous. The dentition, therefore, sufficiently indicates that the species cannot be placed in the Gen. *Lycodon*, to which it has been referred by M.M. H. Boie, Wagler and Schlegel. The young one is of the following dimensions:—

	Inch.
Length of the head,.....	$0\frac{4}{8}$
Do. do. trunk,.....	$8\frac{1}{8}$
Do. do. tail,.....	$2\frac{1}{8}$
	<hr/>
	$10\frac{6}{8}$ inch.

Greatest circumference of the trunk  $\frac{5}{8}$  inch.  
Scuta 201; Scutella 73.

(2366) *COLUBER RADIATUS*, Schlegel.

Russell II. Pl. 42.

*Coluber quadrifasciatus*, Cantor, (Var.).

Head and back light yellowish bay, paler on the sides; the hind head with a transversal black line, branching off along the exterior margins of the occipitals; a black oblique streak behind the eyes, and another beneath them dividing both jaws. On each side of the back a broad longitudinal black band, relieved at intervals by a short network, produced by 3 or 4 scales of each series being edged with pale-brown, and the skin between them white. The bands in some commencing at a distance from the head, are continued or interrupted terminating on the posterior part of the back. Below them is on each side a parallel black line; lips, throat and lower surface yellow. Iris bright gamboge with a concentric black ring. Tongue bluish black.

*Young.*—Above of clearer colours; beneath pearl-coloured.

Scuta 222 to 248; Scutella 82 to 94.

*Habit.*—*Pinang, Singapore, Malayan Peninsula.* Java, Sumatra, Cochin-China, Tenasserim, Assam.

This species is numerous in marshes, and paddy-fields, and often becomes a tenant of out-houses, where during the day it remains concealed, till nightfall favours its pursuit after rats. It

is however equally diurnal, preying upon smaller birds, lizards and frogs. Assam produces a local variety distinguished by 18 instead of 17 longitudinal series of scales, of which the 3 upper ones are all lineated, whereas normally such is the case on those of the posterior part of the body. It makes a vigorous defence, and in darting at an enemy is capable of raising nearly the anterior two-thirds of the body from the ground. In a female were found 23 whitish, soft, cylindrical eggs, of which the largest measured  $1\frac{1}{8}$  inch in length. The largest individual observed was of the following dimensions:

	Feet.	Inch.
Length of the head,.....	0	$1\frac{4}{8}$
Do. do. trunk,.....	5	$3\frac{4}{8}$
Do. do. tail,.....	0	$10\frac{4}{8}$
	<hr/>	<hr/>
	5 ft.	$3\frac{4}{8}$ in.

Greatest circumference  $3\frac{5}{8}$  inch.

Habits and general appearance link the present species to *Col. dhumnades*, Cantor, Chusan,—which is covered by 14 to 16 longitudinal series of rhomboidal scales, of which those of the two-uppermost series commence at a short distance from the head, exhibiting the central raised line, and *Col. mucosus*, Linne (*Col. blumenbachii*, Merrem,) but the latter as well as its variety with uniformly smooth scales (*Col. dhumna*, Cantor: *Spicil.*) utter when irritated a peculiar diminuendo sound, not unlike that produced by a gently struck tuningfork.

(2367) *COLUBER KORROS*, Reinwardt.

*Coluber korros*, Reinwardt, apud Wagler, Schlegel.

Brownish green above, the scales of the posterior part of the trunk and of the tail with black points and edges, producing a regular network; beneath yellowish white or pearl-coloured; the latter part of the scuta light bluish-grey. Iris bright yellow with a bluish grey or blackish concentric ring, tongue black.

*Young.*—Above with some indistinct transversal bands, produced by two lateral white spots on some of the scales; the posterior part of the trunk with dark longitudinal lines.

Scuta 162 to 190; Scutella 79 to 136.

*Habit.*—*Pinang, Singapore, Malayan Peninsula.* Java, Sumatra, Arracan, Tenasserim.

It is numerous in the Malayan vallies. The largest individual measured:

	Feet.	Inch.
Length of the head,...	0	$1\frac{2}{8}$
Do. do. trunk...	2	$6\frac{2}{8}$
Do. do. tail,.....	1	$4\frac{2}{8}$
	<hr/>	<hr/>
	3 ft.	$11\frac{6}{8}$

Greatest circumference of the trunk 3 inches.

Its habits are similar to those of the last mentioned species, from which it is easily distinguish-

# REPTILES OF THE

ed by its 15 longitudinal series of smooth rhomboidal scales with rounded points.

## (2368) COLUBER HEXAHONOTUS, N.S.

Head and back dark brown, changing to pale brownish buff on the side; trunks with numerous, close, transversal black bands, each with a few white spots on the lower parts, becoming indistinct towards the posterior extremity of the trunk, from whence the colour is uniformly dark brown; labial shields yellow, edged with black; beneath yellowish white, scutella edged with brown. Iris gamboge with a black concentric ring; pupil round, tongue black; central series of dorsal scales hexagonal.

Scuta 191; Scutella 148.

*Habit.*—Pinang.

The head is distinct, elongated, with the muzzle broad, truncated, covered above with the normal number of shields, in form resembling those of Col. korros. The eyes are large, prominent, with two præ-orbitals, of which the superior is the larger, the inferior is wedged in between the 3rd, 4th and 5th upper labials. In addition to two post orbitals, there is an elongated crescent-shaped infra-orbital, resting on the 6th and 7th upper labials. The latter are 8 on each side, of which the 5th, broad hexagonal, borders the orbit; the following are elongated, gradually increasing in size. The lower labials, 9 on each side, lie on the chin in contact with two pairs of elongated shields. The nostrils are rather large, orbicular, opening near the margin of the anterior frontals. The frenal is small, obliquely situated between the surrounding shields. The temples are covered by two pairs of elongated shields. The gape is wide, the teeth minute, of equal length. The trunk is slender, much compressed with 17 longitudinal series of smooth, rhombic, sub-imbricate scales, of which the central series is hexagonal. The abdomen narrow, arched. The tail is very slender elongated, tapering to a sharp point.

A solitary individual, discovered by Sir William Norris on the Great Hill of Pinang, was of the following dimensions:—

	Ft.	Inch.
Length of the head,.....	0	0 $\frac{5}{8}$
Do. do. trunk,.....	1	0
Do. do. tail,.....	8	4 $\frac{5}{8}$
	1 ft. 3 $\frac{3}{4}$ inch.	

Circumference of the neck  $\frac{5}{8}$ , of the trunk 1 inch, of the root of the tail  $\frac{3}{8}$ . In fierceness it resembled the preceding species.

## ARBORIAL.

*Gen.* DIPSAS, Laurenti.

Head large, broad, depressed, cordate, covered with shields; neck narrow, trunk much narrower

than the head, compressed, very long, beneath covered with scuta, tail cylindrical, imbricate.

## (2369) DIPSAS DENDROPHILA, Reinwardt.

Scheuchzer, 662, Fig. II. (Col. variabilis, apud Merrem.)

Dipsas dendrophila, apud Wagler.

Dipsas dendrophila, Wagler, apud Horsfield: Life of Raffles.

Dipsas dendrophila, apud Schlegel.

Head, back and sides intense black with steel-blue, lilac, and green reflections; beneath pale black, iridescent; body and tail with numerous bright yellow transversal bands, widened below, sometimes joined on the back or abdomen, occasionally reduced to irregular spots; throat and lips bright yellow, labials with black edges. Pupil elliptical, vertical; iris and tongue black.

Scuta 218 to 225, Scutella 100 to 112.

*Habit.*—Pinang, Singapore, Malayan Peninsula. Java, Celebes.

It inhabits the Malayan hills and valleys, but apparently in no great numbers. The largest individual measured—

	Feet.	Inch.
Length of the head,.....	0	1 $\frac{4}{8}$
Do. do. trunk,.....	3	2 $\frac{7}{8}$
Do. do. tail,.....	1	0
	4 ft. 5 $\frac{3}{8}$ inch.	

Greatest circumference of the trunk, 4 inch.

## (2370) DIPSAS MULTIMACULATA, Schlegel.

Scheuchzer, 657, Fig. 2.

Russell, II. Pl. 23.

Dipsas multimaculata, Schlegel.

Ground-colour, above light greenish grey, minutely spotted and marbled with brown; on the head an angular, backwards diverging black mark with whitish edges; a black oblique line from behind the eyes to the hind head, where it joins a lozenge-shaped black spot with whitish edges; along the back and tail a series of large, irregularly oval, black spots with whitish edges, arranged in close quincunx series; the sides with numerous, similarly coloured, oblique or arched, often interrupted, bands; labials greenish white, black-edged; beneath greenish white tinged with rose-colour, minutely spotted with brown, and with a double or treble lateral series of irregular black spots. Iris pale greenish golden, minutely dotted with black; pupil elliptical, vertical; tongue whitish.

Scuta 202 to 235; Scutella 80 to 106.

*Habit.*—Pinang, Malayan Peninsula. Celebes, Java, Tenasserim, Bengal.

On the hills of Pinang this species appears to be more numerous than the former. The largest individual measured—

## MALAYAN PENINSULA AND ISLANDS.

	Feet.	Inch.
Length of the head,.....	0	$0\frac{5}{8}$
Do. do. trunk,.....	1	$10\frac{4}{8}$
Do. do. tail,....	0	$5\frac{5}{8}$
	2 ft.	$4\frac{7}{8}$ in.

Greatest circumference,  $1\frac{3}{8}$  inch.

The central hexagonal scales are elongated, narrow on the anterior part of the trunk, which is covered by 19 longitudinal series of smooth, lanceolate, imbricate scales; from thence commence 17 series of broader scales.

(2371) *DIPSAS CYNODON*, Cuvier.

*Dipsas cynodon*, apud Boie, Guerin, Schlegel.

*Young*.—Ground-colour yellowish brown, head with a dark black-edged arrow-shaped mark, and a black oblique streak from the eye to the nape of the neck; labials pearl-coloured, edged with black; back with numerous black transversal marks, shaped like two letters Y placed horizontally towards each other or in quincunx, becoming indistinct towards the tail. Beneath pearl-coloured with a black spot near the lateral part of the scuta; scutella edged and minutely dotted with brown.

Scuta 225; Scutella 92.

*Adult*.—Head and back uniformly greyish brown tinged with lilac, with a number of distant large, transversal, purple, bands (the scales edged with black), lozenge-shaped with triangular lateral appendages, becoming indistinct towards the tail, which is alternately brownish buff and purple with black-edged scales. Beneath pale yellow, scutella minutely dotted and edged with brown. Iris pale golden, minutely dotted with purple; pupil elliptical, vertical; tongue whitish.

Scuta 275, Scutella 153.

*Habit*.—*Pinang, Malayan Peninsula. Java, Tenasserim.*

A young one was captured on the Great Hill of Pinang by W. T. Lewis, Esq. An adult, killed in Province Wellesley, was of the following dimensions:

	Feet.	Inch.
Length of the head,.....	0	$1\frac{4}{8}$
Do. do. trunk,....	4	$0\frac{3}{8}$
Do. do. tail, ...	1	4
	5 ft.	$5\frac{7}{8}$ in.

Circumference of the neck  $1\frac{6}{8}$ , of the trunk  $2\frac{4}{8}$  inch.

The young had 21, the adult 23 longitudinal series of smooth, lanceolate, imbricate scales. The long maxillary and palatal teeth are proportionally less developed in the young than in the adult.

(2372) *DIPSAS BOA*, (H. Boie.) (See Plate, Fig. 3.)

*Amblycephalus boa*, H. Boie; Isis.  
*Dipsas boa*, apud Schlegel.

Ground colour above: rose coloured washed with brown, varying in intensity and shade from light bay to umber, prevailing so as to make the ground colour appear as minute spots, and with numerous irregular black spots, confluent on the head; cheeks and lips carnation, with a vertical black streak from the middle of the orbit. Beneath carnation, dotted with umber, sometimes assuming the shape of the large irregular spots. Iris: silvery rose-coloured, lower half dotted with black, pupil elliptical, vertically contracted by the light; tongue whitish.

Scuta abdominalia 164; Scuta subcaudalia 112; or 170 + 109.

*Habit*.—*Pinang, Java.*

The head is depressed, elongated, conical, with the muzzle truncated; the rostral shield is very large, vertically placed; the cheeks compressed, but the lips very tumid below the eyes. Of the nine crown shields the occipitals are distinguished by their reduced size, and frequent subdivision in 2 linear inter-occipitals, bordered by two large polygonal post-occipitals, enclosing a smaller third, linear. Behind the latter appears on each side a small hard tubercle, covered like the rest of the hind head with minute polygonal scales. Each temple is protected by 5 to 6 large shields and as many smaller resting upon the labials. The nasal is large, pyramidal with the rounded nostril in the centre, and the apex wedged in between the 3 frenals, placed obliquely or vertically one above the other. The eye is large, prominent, encircled by the supra-orbital and 7 smaller shields, so that none of the upper labials reach the orbit. The lips are arched, and outwardly appear to reach to the hind head, but the commissure, or the angle of the mouth is situated immediately below the eye, which greatly reduces the opening of the mouth. Of the 9 pairs of upper labials the anterior 6 are narrow, but very deep and bulging; the posterior 3 are broader, elongated; the inferior labials, 11 pairs, are as well as the rostral, greatly reduced by the 3 pairs of very large mentals. The front view of the head grotesquely resembles that of a mastiff. All the teeth are strong, but the front tooth on each side of the lower jaw is longer than the rest; the palatal rows are very close together, and converging. The trunk is much compressed, covered by 13 longitudinal series of scales, of which the dorsal row is composed of very large hexagonal ones, each with a strong keel; the rest are smooth, rhombic, imbricate. The abdomen is very narrow, and the sides of the scuta are bent upwards. The tail is elongated, slender, tapering, and much less compressed than the trunk. Of two individuals from the hills of Pinang, the

# REPTILES OF THE

larger, a male, was of the following dimensions :—

	Feet.	Inch.
Length of the head,.....	0	1
Do. do. trunk,.....	1	11
Do. do. tail,.....	0	11½
	2 ft.	11½ in.

Circumference of the neck 1 inch, of the trunk 1½, of the root of the tail ¾ inch. In a female were observed 4 cylindrical, whitish eggs, each ⅝ inch in length. The stomach contained a few remains of insects.

This species is closely allied to *Dipsas carinata*, Schlegel, (*Amblycephalus*, Kuhl; *Paras*, Wagler,) in which also the dorsal series of scales are keeled. M. Schlegel's short description and figure (Pl. XI, 29, 30) appear to have been taken from an immature specimen.

The preceding four species are very fierce, their mode of attack is that of *Lycodon anlicus*. Kuhl has observed vibrating movements in the tail of *Dipsas multimaculata*, which however are also exhibited by *Dipsas trigonata* (Schneider), (*Col. catenularies*, Daudin,)—*D. cynodon*, Cuvier, and among the venomous serpents, by *Vipera russelii*, (Shaw) and several Asiatic species of *Trigonocephalus*, when they are irritated and preparing to bite.

## Gen. HERPETODRYAS, H. Boie.

Head trigonal, very long depressed, smooth, rather sharp; trunk and tail very elongated; scales, particularly those of the tail, large; those of the back partially carinate; in other respects resembling *Coluber*.

(2373) *HERPETODRYAS OXYCEPHALUS*, (Reinwardt.)

*Coluber oxycephalus*, Reinwardt.  
*Gonyosoma viride*, Wagler.  
*Herpetodryas*, apud Schlegel.

Head above shining dark-green with a blackish straight line from the nostrils to the angle of the mouth: lips and throat pale yellowish green; on the lower part of the sides, all the scales with black edges; the anterior half of the tail, separated from the trunk by a transversal orange band, ochre, gradually changing to greyish brown on the posterior half, all the scales edged with black. Abdominal scuta light yellowish green with pale yellow edges; subcaudal scutella grey with black margins. Eyes moderate, little prominent; iris pale sea-green with a narrow pale yellow inner ring and a transversal black band; pupil circular, black. Tongue ultramarine, divided in the middle by a black longitudinal line. The exposed part of the larynx black.

Scuta 268; Scutella 149.

*Habit.*—Pinang, Java, Celebes.

The shields of the head are elongated, most so the linear frenal. The teeth are numerous; in each row the anterior six or eight are longer than the rest, which gradually decrease. The scales of the trunk, in 25 longitudinal series, are rhombic with rounded points, imbricate, and all smooth except those covering the spinous processes, which are faintly lineated.

Of two individuals from the hills of Pinang, the larger, taken by Sir William Norris, was of the following dimensions:

	Feet	Inch.
Length of the head,...	0	1½
Do. do. trunk,..	3	4
Do. do. tail,....	1	1
	4 ft.	6½ inch.

Circumference of the neck 2, of the trunk 3, of the root of the tail 1½ inch.

The ferocious habits of this serpent have been accurately described by M. Reinwardt. It has in a remarkable degree the power of laterally compressing the neck and the anterior part of the body, when the greyish blue skin becomes visible between the separated scales. In such state of excitement it raises nearly the anterior third vertically from the ground, continues fixed during several seconds with vibrating tongue, and bites. It then throws itself down, to rise to a renewed attack. A similar mode of attack characterises the following species, viz: *Dryinus nasutus*, (Lacepede,) (Russell, I. Pl. 12 and 13,)—*D. prasinus*, (Reinwardt.) (*Dryophis prasina* apud Schlegel,) *Leptophis pictus* (Gmelin), and *Leptophis caudalicatus*.

## Gen. DRYINUS, Merrem, 1820.

[Note. In H. Boie's Genera, published in Isis, 1827, *Dryophis*, (Dahlman,) is substituted for this genus. Wagler in 1830 separated some species and the denomination of *Tragops*, and M. Schlegel in his "Essay" has exclusively retained *Dryophis* although Prof. Thos. Bell already in 1825 had published his article on *Leptophina*, comprising *Dryinus*, Merrem, and *Leptophis*, Bell.]

Upper jaw much longer than the lower; middle attenuated more or less acute at the apex, which in some species is mucronate and moveable.

(2374) *DRYINUS PRASINUS*, (Reinwardt.)

Seba, II, Tab. LIII, Fig. 4,  
*Coluber nasutus*, Shaw, apud Russell,  
II. Pl. 24.

[This specific name was previously applied by Lacepede in 1790 to the other Asiatic species.]

*Dryinus nasutus*, Bell, (not Merrem, 1820.)

*Dryophis prasinus*, Reinwardt.

*Tragops*, Wagler.

*Dryinus nasutus*, Bell, apud Horsfield:  
Life of Raffles.

*Passerita*, Gray.

*Dryophis prasina*, apud Schlegel.

"Ular daun" of the Malays.

# MALAYAN PENINSULA AND ISLANDS.

Leek-green above, with some irregular white and black oblique lines, paler on the cheeks and upper lips; tail cinnamon; under lips and throat white, scuta and scutella light green or mother-of-pearl, on each side with a white or pale yellow longitudinal line, below which in some a second, green line. Pupil black, elongated-pyriform, with the apex turned forwards, horizontally contracted by the light. Iris pale burnished golden, bright on the pupillary margin, the upper half of which forms a little behind its middle a small pointed lobe. Tongue bluish white.

Scuta 186 to 223; Scutella 140 to 203

*Habit.*—*Malayan Peninsula and Islands.* Celebes, Java, Cochin-China, Siam, Tenasserim, Arracan, Bengal, Assam

Var. A.

*Dryophilis xanthozonius*, Kuhl?

Head less elongated and the rostral shield unusually small; upper lips in some white; besides the yellow and green lateral line, a central green; scutella in some with brown edges.

*Habit.*—*Same localities,*

Var. B.

Head above light brownish grey, tinged with sky-blue and rose-colour cheeks and lips pale rose; trunk light brownish ash, changing to pale rust colour on the tail; whitish grey on the sides; beneath buff, with a white longitudinal line on each side. Iris burnished silver; tongue white.

*Habit.*—*Pinang Hills.*

Var. C.

Upper parts saffron yellow, paler on the sides; beneath sulphur-coloured, with a lateral white line. Pupil deep burnished golden; tongue white.\*

*Habit.*—*Pinang Hills.*

This species is exceedingly numerous in the Malayan forests, both in the hills and valleys, preying upon small birds, arboreal lizards, frogs, and in early age upon insects. It may readily be distinguished from *Dryinus nasutus*, (Lacep.) (Merrem, not Bell;—Russell, I. Pl. 12, 13) by two, sometimes 3 frenals on each side. The trunk is covered by 15 longitudinal series of smooth rhomboidal scales with rounded points, imbricate, so as to appear linear; those of the tail are all broad rhombic. The anterior upper maxillary teeth gradually increase towards the sixth, which is the longest, and enclosed in a pointed fold of gingiva. The following teeth, commencing at a short interval, are short, but the last is very long with a furrow on the convex edge. The inferior maxillary teeth also increase in length towards the sixth, the longest, and are protected by a broad triangular scabbard, containing several additional loose teeth; the rest

are uniformly small, commencing at a short interval from the sixth. The palatal are uniformly very short. The largest individual of a great number measured—

	Feet.	Inch.
Length of the head,.....	0	2
Do. do. trunk,.....	4	3 $\frac{5}{8}$
Do. do. tail,.....	2	6 $\frac{1}{8}$

7 ft. 0 $\frac{1}{8}$  in.

Circumference of the neck 1 $\frac{1}{2}$ , of the trunk 2 $\frac{2}{3}$ , of the root of the tail 1 inch.

The varieties, of which B. and C. were from the hills of Pinang, are not numerous, and of a comparatively small size. The very young ones are as gentle as those of a more advanced age are ferocious. Their power of expanding the anterior part of the body and their mode of attack, have been noted under *Herpetodryas oxycephalus*.

*Gen.* LEPTOPHIS, Bell, 1825.

Rostrum obtuse, and the upper jaw projects but very slightly beyond the lower.

(2375) LEPTOPHIS PICTUS, (Gmelin.)

*Coluber pictus*, Gmelin.)

*Coluber decorus*, Shaw.

Russell, II. Pl. 26. Cumberi muken.

*Bungarus filum*, Oppel.

*Dipsas schokari*, Kuhl, (not Forskal.)

*Dendrophis chaireacacos*, H. Boie.

*Dendrophis*, Wagler.

*Dendrophis picta*, Schlegel.

Head and body above bronze with strong golden reflections; skin between the scales of the anterior part of the body alternately ultramarine and black. Lips, throat, the two lowest lateral rows of scales, and the abdominal surface silvery mother-of-pearl. From the muzzle to the root of the tail a black line, bordering above the silvery sides, which below are circumscribed by a second black line, commencing a little behind the head. Iris bright golden with a transversal black line; pupil black, circular, tongue scarlet.

Scuta 167 to 187, Scutella 109 to 149.

*Habit.*—*Malayan Peninsula and Islands.* Manilla, New Ireland, Waigiou, Amboina, New Guinea, Pulo Samao, Java, Sumatra, Cochin-China, Tenasserim, Burmah, Bengal, Assam, Coromandel.

Var. A.

[Note. The variety, *Col. polychrous*, Reinwardt, appears to inhabit neither the Malayan Peninsula nor Bengal.]

*Coluber filiformis*, Linne, (young.)

Fil, Double Raie, Lacepede, (young.)

Russell, II. Pl. 25, Mancas, Rooka, Maniar.

*Coluber bilineatus*, Shaw.

*Leptophis mancas*, Bell.

*Dendrophis maniar*, Boie.

# REPTILES OF THE

*Ahaetula bellii*, Gray, Ill. Ind. Zool.  
*Dendrophis lateralis*, Gray: Ill. Ind. Zool.  
*Chrysopelea boii*, Smith.  
*Dendrophis picta*, Var. Schlegel.  
*Dendrophis boii*, apud Cantor.

Above dull brownish black, with a light brown dorsal line; the two lowest series of scales pale greenish white, forming a lateral band, bordered above by a black line, commencing from the muzzle, more or less distinct, in some irregularly broken up on the anterior part of the body. A second faint black line below. Iris golden, in some dotted with black; tongue black.

*Habit.*—*Malayan Peninsula*. Bengal, Assam, Ceylon.

The species occurs numerous in the Malayan hills and valleys, but the contrary appears to be the case with the plain variety, which in Bengal is equally common. The following must be added to the description of M. Schlegel. The frenal shield is small, rectangular; superior labials 9, inferior 10 or 11, one præ-orbital, two, in some three small post-orbitals. The trunk is covered by 15 longitudinal series of smooth, imbricate scales; the central dorsal series is wedge-shaped, in some almost hexagonal, the next six are linear, but the lowest, as well as all the scales of the tail, are broad rhombic with rounded points. In a female were found seven coriaceous, whitish eggs of an elongated cylindrical shape, each  $1\frac{3}{8}$  inch in length. In habits and mode of attack this species resemble *Dryinus prasinus*, but it is not exclusively arborial. Probably no instance affords a more striking difference in colours, between species and variety than the present: the former with dazzling brilliant livery; the latter in its plain, dull colours. Both attain to similar size: the largest male examined was of the following dimensions:

	Ft.	Inch.
Length of the head,.....	0	$1\frac{1}{8}$
Do. do. trunk,.....	2	6
Do. do. tail,.....	1	1

3 ft.  $8\frac{1}{8}$  inch.

Circumference of the neck  $1\frac{2}{3}$ , of the trunk 2, of the root of the tail, 1 inch.

This serpent appears to possess uncommonly acute hearing, and turns its head in the direction of the sound.

(2376) *LEPTOPHIS CAUDALINEATUS*, N.S.

*Ahaetula caudalineata*, Gray: Illust. Ind. Zool.

*Dendrophis ornata*, Var. Schlegel.

Head, trunk, and tail above light brownish bronze, the scales with black edges; on the posterior half of the trunk four parallel black lines, terminating at the root of the tail, from whence commences a single central black line; sides metallic mother-of-pearl, from a short distance behind the head bordered by two parallel black lines of which the lower, the broader,

covers the lower half of the last series of scales and the lateral part of the scuta; both the lines continue to the apex of the tail. Lips, throat and abdominal surface pale metallic citrine, the tail beneath with a black central line. Iris golden, dotted with brown; pupil round; tongue bluish white, the forked part black.

*Young.*—Upper parts of the body Indian red, with metallic reflections.

Scuta 183 to 188; Scutella 105 to 110.

*Habit.*—*Penang, Singapore*.

The head large, less depressed than in the preceding species, the muzzle broad, blunt; cheeks tumid; all the shields of the crown are short and broad, except the vertical which is laterally arched, and very narrow behind. There is a single elongated post-occipital, and the rest of the hind head is covered with broad hexagonal shields. Each temple is covered by two pairs of large shields, in front of which a pair of very minute ones, bordering upon the equally small post-orbitals. The eye is large, prominent; the præ-orbital and the linear frenal proportionally small; the nostrils large, opening in the middle of the nasal; the rostral broad slightly arched beneath. The labials, 9 on each side of both jaws, resemble those of the preceding species. The mouth is large; the maxillary teeth strong, distant. In the lower jaw the anterior ones gradually increase in length till the fourth, which appears like a canine, the rest as well as the palatal teeth are all smaller, of uniform length. The chin is covered by the second pair of labials and two pairs of mentals, of which the posterior pair is elongated. The trunk is strong, less compressed than in the preceding species, with 13 series of smooth imbricate scales, of which the two lowest series are large rhombic with rounded points, the next four elongated rhomboidal (linear), and the odd central dorsal rhomboidal, not larger than the rest. The tail is covered with broad hexagonal, not imbricate, scales. The abdomen is narrow, flattened, the centre part of the scuta with strongly arched margins; the sides turned upwards and forming a continued sharp lateral ridge. The tail is slender, tapering; its vertical section nearly square.

Of this species but two individuals were observed: a young one at Singapore, an adult on the Great Hill of Pinang. The latter measured—

	Feet.	Inch.
Length of the head,.....	0	$1\frac{2}{3}$
Do. do. trunk,.....	3	$5\frac{6}{8}$
Do. do. tail,.....	1	2

4 ft. 9. in.

Circumference of the neck 2, of the trunk  $3\frac{5}{8}$ , of the root of the tail  $1\frac{1}{8}$  inch.

In its mixed arborial and terrestrial habits and in fierceness it resembles *L. pictus*, but its power

of compressing and expanding the forepart of the body is somewhat limited.

This species appears somewhat to approach to *Leptophis formosus*, (*Dendrophis formosa*, Schlegel,) but besides other distinguishing characters, it differs from that, and all other Asiatic species in having but 13 series of scales. The indifferent figure of *Ahoetula caudolineata* in Illustrations of Indian Zoology, which appears to be all which has been published concerning this species, has led M. Schlegel to suppose it was intended to represent a variety of *Leptophis pictus*, although the black outline of the head is correct.

(2377) *LEPTOPHIS ORNATUS*, (Shaw.)

Scheuchzer, T. 606.

Seba, 1. T. 94, Fig. 7.—II. T. 7, Fig. 1; T. 61, Fig. 2.

Russell, II. Pl. 2, Kalla Jin.

*Coluber ornatus*, Shaw.

*Coluber ibiboboca*, Daudin.

*Coluber ornatus*, Merrem, apud Horsfield: Life of Raffles.

*Chrysopelea paradisi*, H. Boie.

*Dendrophis ornata*, Schlegel.

*Habit.*—Bengal, Ceylon.

VAR.

Ular Chindi, Raffles.

*Dendrophis chrysochloros*, Reinwardt, (young.)

Head above intense velvety black, with three or four distant transversal bands, and numerous irregular spots of gamboge or sulphur colour; all the scales with an oval gamboge spot; from the hind head to the point of the tail a number of large rounded vermilion spots; lips, throat and abdominal surface greenish-gamboge, scuta and scutella with black margins. Iris and tongue black.

Scuta 198 to 236. Scutella 113 to 147.

*Young.*—Head, trunk and tail above greenish olive, with a series of transversal black bands in pairs; the intervals between the bands vermilion; the sides with numerous distant, irregular, small black spots; lateral part of the scuta and scutella white, the side and the anterior margin black; the centre part pale greenish yellow; scutella partially edged with black, and with a central light blue line. Tongue vermilion, the forked part black.

*Habit.*—Pinang, Malayan Peninsula. Java, Sumatra, Tenasserim, Arracan.

The variety, in which the black colour prevails, appears to be confined to the more southern countries, while that with yellow ground colour preponderating, the one described and figured by Russell, occurs in Bengal. The latter has the tongue alternately vermilion and black. Individuals without the frenal shield are not uncommon, and such was the one described by H. Boie as a distinct species (*Chrysopelea paradisi*.) It inhabits the Malayan hills and valleys, but is there, apparently less numerous than in Bengal.

The largest male observed was of the following dimensions:—

	Feet	Inch
Length of the head,.....	0	1 $\frac{1}{8}$
Do. do. trunk,.....	2	7 $\frac{3}{8}$
Do. do. tail,.....	0	11 $\frac{4}{8}$

3 ft. 8  $\frac{3}{8}$  Inch.

Circumference of the neck 1  $\frac{1}{8}$ , of the trunk 1  $\frac{7}{8}$ , of the root of the tail  $\frac{7}{8}$  inch.

The trunk is covered by 17 longitudinal series of smooth, imbricate rhomboidal scales, with rounded points. It is but seldom seen in trees; it is more frequently found on the ground in the grass, watching for its prey: lizards (*Geckonidae*,) [Note. Vide *Ptychozoon homalocephalum*, supra.] and frogs. The female has 6 to 8 white, elongated cylindrical eggs, about 1  $\frac{1}{8}$  inch in length. It differs from the other species in its being deprived of the power of compressing, and expanding the anterior part of the body, and its gentleness. The young ones never attempt to bite, the adult but seldom, and without raising vertically the anterior part of the body. In the latter, the four anterior teeth of the lower jaw are a little longer than the rest, which are uniformly small.

AQUATIC.

*Gen.* TROPIDONOTUS, Kuhl.

Head oblong ovate, rather indistinct, depressed; nostrils between the sutures of two shields; eyes moderate, with circular scales pupil, of the back lanceolate ovate, imbricate; trunk elongated, cylindrical, tail moderately long, tapering.

(2378) *TROPIDONOTUS UMBRATUS*, (Daudin,) Var.

*Tropidonotus trianguligerus*, Schlegel.

Above shining brownish, or yellowish green-olive; lips gamboge with a black oblique line between the sixth and seventh labials, a second from the orbit to the angle of the mouth: a third from the under lip to the upper part of the neck; trunk and tail with black spots, in some very minute, irregular, in others larger, approaching to quincunx order; the sides with numbers of large square or triangular scarlet spots, separated from each other by broader or narrower black vertical bands. Scuta and scutella gamboge with black margins, the latter with a black central line. Iris black with a narrow golden circle; tongue black.

Scuta 121 to 130; Scutella 76 to 84.

*Habit.*—Malayan Peninsula and Islands. Java, Bengal.

The vertical and supra-orbital shields are of an elongated narrow form; the anterior frontals triangular, longer than broad; the nostrils small, placed high on the sides, the frenal is elongated pentagonal, with the largest margin touching the præ-orbitals. Of the three post orbitals the

lowest is the longest, wedged in between the fifth, sixth, and seventh upper labials, of which the fifth is the only one which reaches the orbit; the eye is moderate, prominent; the upper labials are 9, the lower 11 on each side. The mouth is very large, the teeth small, crowded, except the two last of the upper jaw, which are longer than the rest. The trunk is slightly compressed, covered by 19 longitudinal series of scales, of which the two lowest are broad rhombic, the rest elongated rhomboidal with rounded points, those of the back lineated. The abdomen is broad arched. This variety differs in nothing but colours from *Tropidonotus umbratus*,\* (Daudin), and to judge by the description of M. Schlegel, it appears to be identical with *T. trianguligerus*. In the Malayan valleys the variety is very numerous; in Bengal it is less so, but there the species abounds in and near fresh water, where it preys upon fishes and frogs. The variety attains to a size similar to that of the species, both of which are equally fierce.

[\* Note. Russell II. Pl. 3. Dooble, young.—Pl. 5. Dora, adult.—Col. umbratus, Daudin.—Col. dora, Daud.—Col. brunneus, Hermann.—Col. atratus, Herrm.—Col. lugubris, Merrem.—*Tropidonotus umbratus* Schlegel.—*Tropidonotus dora*, apud Cantor.]

The largest individual was of the following dimensions:

	Ft.	Inch.
Length of the head,.....	0	1 $\frac{2}{8}$
Ditto. ditto. trunk,.....	1	9 $\frac{5}{8}$
Ditto. ditto. tail,.....	0	9 $\frac{3}{8}$
2 ft. 8 $\frac{2}{8}$ inch.		

Circumference of the neck 2, of the trunk 2  $\frac{1}{8}$ , of the root of the tail 1  $\frac{5}{8}$  inch.

(2379) *TROPIDONOTUS STOLATUS*, (Linnæ.

Seba, II, Tab. 9, Fig. 1, 2.

*Coluber stolatus*, Linnæ.

Le Chayque, Daubenton, Lapeyre.

Russell, I. Pl. 10, 19.

La vipere chayque, Latreille.

*Coluber stolatus*, Lin., apud Shaw, Daudin.

*Coluber taniolatus*, Daudin.

*Natrix stolatus*, Merrem.

*Tropidonotus stolatus*, Grey, Schlegel.

Head shining brownish olive with several black spots in the sutures of the shields: lips gamboge with several black oblique streaks; head and trunk brownish olive with numerous distant black transversal bands, becoming indistinct towards the tail, and intersected by two parallel bands of a pale ochre or buff, the scales of which on the anterior part of the body edged with black. Beneath gamboge or mother-of-pearl; in some the scuta with a small lateral black spot, or edged with black. Iris black with a narrow golden ring; tongue black.

Scuta 143 to 153; Scutella 69 to 79.

*Habit.*—*Pinang, Malayan Peninsula.* Philippines, Tenasserim, Bengal, Assam, Nipal, Coromandel, Ceylon, Bombay.

The species, so exceedingly numerous in Bengal, is but rarely seen in the Malayan valleys. It is of very gentle habits, and feeds upon young frogs and toads. The largest male observed was of the following dimensions:—

	Ft.	Inch.
Length of the head,.....	0	0 $\frac{7}{8}$
Do. do. trunk,.....	1	4 $\frac{2}{8}$
Do. do. tail,.....	0	5 $\frac{1}{8}$
1 ft. 10 $\frac{2}{8}$		

Circumference of the neck,  $\frac{7}{8}$ , of the trunk 1  $\frac{1}{8}$ , of the root of the tail  $\frac{5}{8}$  inch.

The female has 6 small cylindrical white eggs, each about half an inch in length.

(2380) *TROPIDONOTUS SCHISTOSUS*, (Daudin)

Russell II. Pl. 4. Chittee.

*Coluber schistosus* Daudin.

*Tropidonotus schistosus*, Schlegel.

*Tropidonotus moestus*, Cantor.

Above blackish olive, some with an indistinct blackish line from behind the eye along the side; the lips, the two lowest series of scales on each side, and the abdominal surface whitish yellow. Iris black with a narrow golden ring; tongue small, flesh coloured.

VAR.

*Tropidonotus surgens*, Cantor.

Above bright greenish olive, with a black serrated lateral line.

Scuta 148; Scutella 23.

*Habit.*—*Malayan Peninsula.* Philippines, Tenasserim, Bengal, Madagascar.

The shields of the head are short; there is but a single anterior frontal, of a triangular shape, truncated in front; the frontals are small pentagonal; the nasals nearly equal to the latter; the small semicircular nostrils almost vertical and appearing linear as they are provided with a valvule as in *Homalopsis*; from the lower part of the nostril a minute arched groove descends to the inferior margin of the shield; the frenal is small; the præ-orbital in length nearly equals the three post-orbitals. The scales of the trunk are disposed in 17 longitudinal series, of the two lowest on each side are hexagonal, each scale with a minute round protuberance near the apex; the scales of the next two series present a raised line terminating in a protuberance, but the remaining scales are elongated rhomboidal with truncated, slightly notched points, keeled, imbricate. These marks become indistinct when the integuments are about to be changed, which probably caused them to escape the notice of Russell. The species is not numerous in Bengal, and

# MALAYAN PENINSULA AND ISLANDS.

apparently less so on the Malayan Peninsula. The largest individual measured.

	Feet.	Inch.
Length of the head,...	0	1
Do. do. trunk,...	2	0 $\frac{4}{8}$
Do. do. tail,.....	0	2 $\frac{4}{8}$
	2 ft.	4 Inch.

Circumference of the neck 1  $\frac{6}{8}$ , of the trunk 2  $\frac{4}{8}$ , of the tail 1  $\frac{5}{8}$  in.

The length of the tail is very variable: in some it is contained 3  $\frac{1}{2}$ , in other 6 times in the entire length. This species is very fierce, and prepares to attack by raising the head 3 or 4 inches vertically from the ground, and it has the power of flattening and laterally expanding the skin of the anterior part of the body, like *Naja*, but in a much slighter degree. It bites uttering a faint hissing sound. Frogs and fishes form its food.

## (2331) TROPIDONOTUS CERASOGASTER.

*Psammophis cerasogaster*, Cantor.

Above yellowish brown with pale golden reflections; lighter on the sides, the scales of which in some partially edged with yellow; cheeks, lips, throat and abdominal surface cherry-coloured, with a bright yellow lateral line from the muzzle to the point of the tail. Iris and tongue cherry-coloured.

Scuta 144 to 149; Scutella 60 to 69.

*Habit.*—*Malayan Peninsula*. Bengal, Assam.

The head is elongated, depressed; sides angular, compressed; muzzle truncated; rostral broad, hexagonal, nearly vertical, arched below; the anterior frontals the smallest, next to them the frontals; the rest of the crown-shields are narrow, elongated; each occipital bordered by two pairs of elongated temporals, below which three smaller. Nasals rectangular, placed at a right angle with the anterior frontals; nostrils moderate, prominent. Besides three post-orbitals, there is a minute infra-orbital wedged in between the fifth and sixth upper labials, of which but a small portion of the sixth touches the orbit below. The lips are straight, turned up near their commissure, covered with 8 or 9 pairs of upper, 10 lower shields. The mouth is large; the teeth small, crowded, of equal length. The trunk is cylindrical, compressed, covered with 19 longitudinal series of imbricate, elongated rhomboidal scales with rounded, slightly notched points, keeled except the two lowest series on each side, which are longer than the rest, rhombic, smooth. The abdomen is broad, arched; the tail robust at the root, cylindrical, tapering to a sharp point. A solitary individual from Province Wellesley was of the following dimensions:

	Ft.	Inch.
Length of the head,...	0	0 $\frac{7}{8}$
Do. do. trunk,.....	1	5 $\frac{7}{8}$
Do. do. tail,.....	0	6 $\frac{1}{8}$

2 ft. 0  $\frac{7}{8}$  inch.

Circumference of the neck  $\frac{7}{8}$ , of the trunk 1  $\frac{4}{8}$ , of the root of the tail  $\frac{7}{8}$  inch.

In Bengal this species is not numerous. It is very fierce, attacks in a vertical attitude but without expanding the anterior part of the body. Its food is that of the preceding. The elongated angular head makes this species resemble a *Psammophis*.

## (2332) TROPIDONOTUS JUNCUS, N.S.

Head above shining light brown, lips and throat gamboge; from the angle of the mouth an oblique gamboge band, both joining under a sharp angle on the neck; trunk and tail dull greyish olive, with a series of distant rounded whitish spots on each side; each scutum and scutellum with a small black spot on the sides, which as well as their anterior margins are minutely dotted with brown. Iris black with a golden ring; tongue, small, greyish.

Scuta 157; Scutella 88.

*Habit.*—*Pinang*.

The head is elongated ovate, with the sides angular, compressed; the muzzle truncated; the rostral shield moderate, square, deeply arched beneath, vertically fixed; the anterior frontals small, tetragonal; the frontals larger, angularly bent over the side, where they border the small square frenal; the other crown shields are rather small, the occipitals on each side bordered by small elongated shields, like the rest of the temples; the eyes large, prominent; præ-orbital one; post orbitals three; nasal rectangular; nostrils lateral, large, rounded; upper labials 9, of which the fourth, fifth and sixth border the orbit; lower labials 11; mentals two pairs, elongated. The lips are slightly arched, the mouth wide; the teeth small, crowded; the last upper maxillary tooth longer than the rest. The trunk is very slender, cylindrical, with the centre of the back raised, forming a sharp ridge, the sides bulging near the abdomen, which is arched. The scales are imbricate, very elongated rhomboidal with the apex notched, except the two lowest series on each side, which are broad rhombic; they are all sharply keeled, and disposed on the anterior part of the trunk in 19, on the middle part in 17 longitudinal series. The tail elongated, cylindrical, very slender, tapering to a fine point. A single individual observed on the Great Hill of Pinang by W. S. Lewis, Esq. was of the following dimensions:

	Feet.	Inch.
Length of the head,.....	0	0 $\frac{6}{8}$
Do. do. trunk,....	1	7
Do. do. tail,.....	0	7 $\frac{4}{8}$

2 ft. 3  $\frac{1}{8}$  Inch.

Circumference of the neck  $\frac{7}{8}$ , of the trunk 1  $\frac{1}{8}$ , of the root of the tail  $\frac{7}{8}$  inch.

Like most of the Asiatic species of this genus, the present is of fierce habits. It twice appro-

vokedly bit a wood cutter who happened to pass it. The bite, of course, was productive of no consequences except a slight momentary pain. The very slender make and the elongated tail are characters which approach this species to the arboreal Colubridæ.

*Gen. HOMALOPSIS*, apud Schlegel.

(Erpeton, Lacepede, 1803.—*Rhinopirus*, Merrem, 1820.—*Pseuderyx*, Fitzinger, 1826.—*Homalopsis*, Kuhl, 1827.—*Cerberus*, Cuvier, 1829.—*Hypsirhina*, Wagler, 1830.—*Hydrops*, Wagler, 1830.—*Helicops*, Wagler, 1830.—*Potamophis*, Cantor, 1836.)

*Homalopsis*, Kuhl. Nostrils opening vertically in the centre of the small nasals, with a valvule, crown shields small; dorsal scales imbricate keeled; chin with small shields, throat scaly; labials narrow; abdomen with scuta; tail short, tapering to a sharp point; beneath with scutella.

(2383) *HOMALOPSIS RHINCHOPS*, (Schneider.)

Seba, II. T. 15. F. 3.

Hurria schneideriana Daudin.  
Coluber schneiderianus, Daudin.  
Coluber cerberus, Daudin.  
Python rhynchops, Merrem.  
Python elapiformis, Merrem.  
Python molurus, Merrem.  
Coluber obtusatus, Reinwardt.  
Cerberus (*Homalopsis obtusatus*), Cuvier.  
*Homalopsis schneiderii*, Schlegel.  
Cerberus cinereus, Cantor.

*Young*.—Ash-coloured above, the head with black irregular spots and a short black line behind the eyes; trunk and tail with numerous distant black transversal bands; lips and throat white, dotted with black; the three or four lowest series of lateral scales white; beneath white with a black undulating band, frequently interrupted.

*Adult*.—Ash, lead-coloured or blackish grey with the black marks indistinct or invisible. Iris black; pupil elliptical, vertically contracted by the light; tongue very small, pale greyish.

Scuta 143 to 156; Scutella 49 to 72.

*Habit*.—*Malayan Peninsula and Islands*. New Guinea, Amboina, Timor, Sarapua, Java, Sumatra, Tenasserim, Bengal, Coromandel.

The shields of the upper part of the head, which appear to be of a constant form, are the nasals, the frontals, which enclose the small pair of triangular anterior frontals, (sometimes soldered together,) and the supra-orbitals. The rest are broken up in small, irregular, smooth pieces, differing in outline in each individual. The small eye, placed in a partly vertical, partly lateral

position, is surrounded by a præ-orbital a post-orbital and two or three infra-orbitals. The frenal is comparatively, large, irregularly tetragonal. The anterior seven upper labials are narrow, very high; the posterior five or six each divided in two. A similar arrangement is observed in the inferior 13 or 14 of which the posterior 6 or 7 are very small. On the chin there is a pair of elongated shields immediately behind the 2 pair of labials. The posterior upper maxillary tooth is longer than the rest, and furrowed. The three anterior teeth in the lower jaw are longer than the rest. The trunk is covered with imbricate, finely lineated and keeled scales, of a rhomboidal form with rounded points, disposed on the anterior part in 25, on the posterior part in 17, longitudinal series. The tail is robust, tapering, and prehensile. In the Malayan countries this species occurs in numbers in rivers, estuaries, and occasionally along the sea coasts. It feeds upon fishes. Single individuals measuring between 3 and 4 feet in length, are of very rare occurrence. Of a great number the largest was of the following dimensions:

	Feet.	Inch.
Length of the head,.....	0	1 $\frac{2}{3}$
Do.  trunk,.....	2	3
Do. do. tail,.....	0	7

2 ft. 11  $\frac{2}{3}$  Inch.

Circumference of the neck 1  $\frac{7}{8}$ , of the trunk 3  $\frac{3}{8}$ , of the root of the tail 1  $\frac{3}{8}$  inch. It is of peaceful habits; the female brings forth 8 living young, each of which measures from 7 to 7  $\frac{1}{2}$  inches in length.

(2383b) *HOMALOPSIS BUCCATA*, (Linne.)

Scheuchzer, Pl. 660. Fig. I, (Young.)  
Seba, II. Tab. 12. F. 1;—T. 1;—T. 21.  
F. 3, (Young.)  
*Coluber buccatus*, Linne.  
*Coluber monilis*, Linne.  
*Coluber subalbidus*, Boddaert, apud Gmelin.  
Le Demicollier, Lacepede.  
*Vipernkopfige Natter*, Merrem.  
*Coluber buccatus*, apud Shaw.  
Russell, II, Pl. 33, (Young.)  
*Coluber viperinus*, Shaw.  
*Coluber buccatus*, Daudin.  
*Coluber horridus*, Daudin.  
*Echidna semifasciata*, Merrem.  
*Homalopsis buccata*, Schlegel.

*Young*.—Ground colour, white or buff, becoming brownish on the crown shields, hind head and lips; on the muzzle an angular mark, with the apex between the frontals, Van Dyke brown or chestnut; an oblique streak proceeds from the eye over the cheek, joining a broad cervical band, which, sending a narrow straight line to the occipitals, gives the upper part of the head a heart-shaped outline; the back and tail with numerous broad transversal brown bands, between which the ground colour appears in the shape of white,

often interrupted, narrow bands, and of a white spot in the centre and on each side of the brown bands. The latter reach but as far as the lowest four or five series of scales on the sides, which as well as the throat and abdomen are white; on each side of every third or fourth scutum a brown spot; Scutella black, or white closely spotted with black.

*Adult.*—The livery of the young indistinct: the ground colour of the upper parts pale greyish brown or olive; the bands of a darker shade of the same colour, edged with black; sides and beneath impure buff, the brown marks pale. Pupil black, elliptical, vertically closed by the light; tongue small whitish.

Scuta 155 to 167; Scutella 73 to 89.

*Habit.*—*Pinang, Malayan Peninsula.* Java.

From the small, nearly vertically opening nostrils, proceeds a furrow downwards to the lower margin of the nasal. The anterior frontal is either entire and of a large rhombic shape, or consisting of two triangular shields; the frenal is elongated, rectangular, the small eye is situated more laterally than in the preceding species, and surrounded by two post-orbitals, one præ-orbital, and two infra-orbitals. The seven anterior upper labials are very high, the posterior five or double; of sixteen or seventeen lower labials, the nine anterior are the highest. The last tooth in the upper jaw is furrowed, and as well as the 3 or 4 anterior palatal and inferior maxillary teeth, longer than the rest. The folds of gingiva enveloping the teeth are very ample, and contain in addition to the fixed, numerous, 5 to 6 deep, accessory teeth. The chin is covered by four pairs of elongated scales, decreasing in length from the centre towards the labials. The scales of the trunk are rhombic, imbricate, slightly keeled and finely lineated, disposed on the anterior part in 39, on the posterior in 25 longitudinal series. The tail is robust, tapering and somewhat prehensile. The largest individual observed was of the following dimensions:

	Feet.	Inch.
Length of the head, . . . . .	0	$1\frac{1}{2}$
Do. do. trunk, . . . . .	1	11
Do. do. tail, . . . . .	0	7
		<hr/>
		2 feet. $7\frac{1}{2}$ in.

Circumference of the neck 2, of the trunk  $3\frac{1}{2}$ , of the root of the tail  $1\frac{1}{2}$  inch.

In the valleys of Pinang and on the opposite continent, this species is numerous in streamlets, tanks and in the irrigated fields, where it feeds on fishes. The young ones are very gentle, and the old but seldom bite. In their movements they are sluggish, and on dry land very awkward. The female brings forth six or eight living young

at the time, each between 7 and 8 inches in length.

Hypsirhina, Wagler. Resembling Homalopsis in the form and situation of the nostrils, the integuments and general appearance of the head, trunk, and tail; but the dorsal scales are smooth, and the labials are square, equal; (frenal one.)

(2383c) HOMALOPSIS SIEBOLDI, Schlegel.

Seba, II, Tab. 46, Fig. 2?

*Young.*—Ground colour, white, which on the upper part of the head appears in the shape of two lines diverging from the muzzle over the eyes to the sides of the head. From each side of the vertical shield a line diverging towards the hind head, where it branches in two, sending a portion transversely to the throat, and another to the upper part of the neck joining under an angle that of the opposite side; on the trunk and tail the ground colour shows itself as numerous narrow, transversal bands, which on the centre are frequently interrupted and placed in quincunx series: on the sides the bands are bipartite. The intervals between the ground colour are chestnut with dark brown edges. The lips and the abdominal surface white with numerous pale brown irregular spots. Iris greyish with a transversal black bar; pupil elliptical tongue white.

[Note. *Adult.*—A preserved specimen in the Museum of the Asiatic Society differs from the young in having the head above of a uniform colour, while the rest of the peculiar design is retained. The ground colour is yellowish white; the brown of the young is faded to a dull lead grey.—Scuta 156, Scutella 55.—Dimensions: head  $0\frac{7}{8}$  inch; trunk 1 ft.  $8\frac{2}{3}$  inch; tail  $3\frac{7}{8}$  inch = 2 ft. 1 inch.—Circumference of the neck,  $1\frac{7}{8}$ , of the trunk  $2\frac{5}{8}$ , of the root tail,  $1\frac{1}{2}$  inch. The locality from whence this specimen was obtained, is not known: Bengal is given by M. Schlegel.]

Scuta 155; Scutella 48.

*Habit.*—*Malayan Peninsula.* Bengal.

The description is taken from a solitary young individual, which was killed in Province Wellesley. It measured,

	Inch.
Length of the head, . . . . .	$0\frac{4}{8}$
Do. do. trunk, . . . . .	$5\frac{7}{8}$
Do. do. tail, . . . . .	$1\frac{5}{8}$

---

8 inch.

Circumference of the neck  $\frac{5}{8}$ , of the trunk  $\frac{7}{8}$ , of the root of the tail  $\frac{4}{8}$  inch.

In livery and in general appearance this species resembles *H. buccata*, from which it differs in the following particulars. Both the upper and the lower rostral shield are very small; the anterior frontals are much broader than long,

# REPTILES OF THE

each like a small transversally placed cone, surrounded by the nasal, (with a slit towards the lower margin,) the tetragonal frenal, and behind, by the frontal. The vertical in extent nearly equals each of the short occipitals. The eye is rather large, prominent, surrounded by a single elongated, arched præ-orbital and two post-orbitals, of which the inferior is the larger, bordering the fifth and sixth upper labials of the latter there are eight on each side: the fourth borders the eye below, the two posterior are broken up in small pieces. Of the 11 or 12 pairs of lower labials, the four nearest the angle of the mouth are the smallest. The chin is covered by three pairs of oval shields, of which the anterior is the largest, and by some minute scales. The mouth is small; the teeth minute, uniform, except the last upper maxillary tooth, which is the longest with a furrow on the convex margin. The back is slightly angular in the centre, much depressed; the sides bulging; the abdomen narrow. The anterior part of the trunk is covered with 29, the posterior with 19 series of small smooth, imbricate scales, all rhombic with rounded points. The tail is tapering and compressed.

## (2383d) HOMALOPSIS ENHYDRIS. (Schneider.)

Russell, l. Pl. 30. Mutia Pam, Ally Pam.

Hydrus enhydris, Schneider.

Enhydris cœrulea, Latreille.

Hydrus alrocœruleus, Shaw.

Coluber pythonissa, Daudin.

Homalopsis aer, \* Boie.

Hypsirhina, Wagler.

Potamophis lusingtonii, Cantor.

Homalopsis aer, Schlegel.

Homalopsis olivaceus, Cantor.

[\* Note. This specific name of aer is singularly ill chosen, as the denomination "ular ayer," (water-serpent,) is applied by the Malays to all fresh water serpents. The word "ayer" applied to a single species is as eligible as would be "aqua," eau or "wasser."]

Iridescent dark greenish or brownish-olive above; the scales edged with black; in some two parallel light greyish lines from between the eyes to the tip of the tail; the lower half of the sides pale greenish or brownish-grey; lips and throat white, edged and dotted with black abdominal surface white or buff, with a greenish or brownish line on each side, and a black central line dividing the scuta and scutella. Iris greyish or pale olive; pupil circular; tongue whitish.

*Young*: with lighter and more strongly iridescent colours than the adult.

Scuta 148 to 167; Scutella 53 to 71.

*Habit.*—*Malayan Peninsula and Islands.* Java, Tenasserim, Bengal, Coromandel.

The head is small, ovate, scarcely distinct; the nostrils are hemispherical, with a slit towards the external margin of the shields; the single anterior frontal is small, rhomboidal, much broader than long; the eye is ra-

ther large, prominent, lateral and surrounded by two rather broad post-orbitals, one or two narrow præ-orbitals, and beneath by the fourth upper labial; the frenal is small, rhombic. The external margins of the occipitals are bordered by three elongated shields, and each temple by five similar. The eight upper labials are larger than the ten lower. The chin is covered by two central pairs of elongated shields, between which and the labials is, on each side, a single very elongated shield. The mouth is small, the teeth minute, numerous and equal, except the last tooth of the upper jaw, which is longer than the rest and furrowed. The trunk is very robust, broadly depressed; the sides obliquely compressed, and the abdomen very narrow, flattened. The scales are broad rhomboidal with rounded points, slightly imbricate, and disposed on the anterior part in 25, in the middle in 21, and near the tail in 19 longitudinal series. The tail is very slender, somewhat compressed, tapering and prehensile. The largest individual was of the following dimensions:—

	Fect.	Inch.
Length of the head,.....	0	1
Do. do. trunk,.....	1	5 $\frac{3}{8}$
Do. do. tail,.....	0	5 $\frac{2}{8}$
		2 feet.

Circumference of the neck 1 $\frac{2}{8}$ , of the trunk 2 $\frac{2}{8}$ , of the root of the tail  $\frac{7}{8}$  inch.

Numbers of this species may be seen in rivers, as well as in irrigated fields and estuaries, preying upon fishes, which however it refuses in a state of captivity. It is of timid and peaceful habits. A large female, after having been confined upwards of six months in a glass vessel filled with water, brought forth eleven young ones in the manner noted above under *Acrochordus javanicus*. During the progress she lay motionless on the bottom of the vessel, the anterior part of the abdomen was retracted towards the vertebral column, while the muscles of the posterior part were in activity. Shortly after the parturition she expired under a few spasmodic movements, and also two of the young ones died in the course of about two hours, after having, like the rest, shed the integuments. In length they varied from 6 inch to 6 $\frac{3}{8}$ . The living nine presented a singular appearance: they remained a little way below the surface of the water coiling themselves round the body of an adult male, which was also kept in the vessel, occasionally lifting the heads above the surface to breathe, at the same time resisting the efforts of the senior to free himself. Fishes and aquatic insects were refused, in consequence of which the young ones expired from inanition in the course of less than two months.

## MALAYAN PENINSULA AND ISLANDS.

(2383e) HOMALOPSIS PLUMBEA, Boie.

Hypsirhina, Wagler.

Hypsirhina hardwickii, Gray: Illust. Ind. Zool.

Homalopsis plumbea, Schlegel.

Iridescent dark brownish, or greyish-olive above, uniformly or with small irregular black spots; the two or three lowest series of scales yellowish, each scale spotted or edged with brown; lips and throat yellow; scuta and scutella yellowish white, the former in some partially edged with black, the latter with a black central zig-zag line; iris grey; pupil elliptical, vertically contracted by the light; tongue whitish.

Scuta 125 to 126; Scutella 36 to 44.

*Habit.*—Pinang. Java.

The head is broad, ovate, depressed; the muzzle blunt, the nostrils small triangular, with a slit towards the lower margin of the nasal; the single anterior frontal broad triangular; the rest of the crown shields are of normal form. The eye is small, placed in a half lateral half vertical position, enclosed by two post-orbitals, one elongated præ-orbital, and beneath by the fourth upper labial; the frenal is very small, tetragonal; the upper labial eight, rather high; lower labials ten; on both jaws the shields increase in size towards the angle of the mouth. The chin is covered with two pairs of elongated shields and a few gulars. The mouth is small; the posterior upper maxillary tooth longer than the rest, furrowed, and the anterior lower maxillary teeth also exceed the following. In addition to the fixed teeth there are several accessory series. The trunk is nearly cylindrical, slightly depressed, covered with small rhombic scales, smooth, and not imbricate, disposed on the anterior part in 19, on the posterior part in 17 longitudinal series. The tail is short, conic, tapering and slightly prehensile. Two individuals, taken at different times in rivulets in the valley of Pinang, in habits resembled *H. rhynchops*. The larger was of the following dimensions:

	Ft.	Inch.
Length of the head,.....	0	$1\frac{1}{8}$
Do. do. trunk,....	1	5
Do. do. tail,.....	0	$2\frac{3}{8}$
	1 ft.	$8\frac{7}{8}$ in.

Circumference of the neck  $1\frac{5}{8}$ , of the trunk  $2\frac{1}{8}$ , of the root of the tail  $1\frac{1}{8}$  inch.

(2383f) HOMALOPSIS LEUCOBALIA, Schlegel.  
Var. (See Plate XL. Fig. 5.)

*Young.*—Above light brownish olive or greenish grey with single irregular distant brown spots; lips and throat whitish yellow; the lowest three or four lateral series of scales, and the abdominal surface greenish white or pearl-coloured.

*Adult.*—Uniformly blackish olive above, otherwise like the young. Iris dark brown; pupil elliptical, vertically contracted by the light. Tongue whitish.

Scuta 130 to 143; Scutella 26 to 37.

*Habit.*—Pinang, Malayan Peninsula.

The head is very broad, depressed, and the muzzle black; the rostral broad, hexagonal, very slightly arched beneath; the superior margin borders the single small elongated anterior frontal, which is of a narrow hexagonal form, broader behind, where it is wedged in between the two broad frontals. The nasals are rather large; nostrils small crescent-shaped, the vertical very broad, short, hexagonal; occipitals large, elongated with a pair of very broad shields on each side, below which the temple are covered by three smaller shields. The eye is very small, in a half vertical position, with two post-orbitals, one præ-orbital, which extends to the large oval nasal; frenal none, or, when present, excessively minute. Of the five large upper labials, the anterior is the smallest and borders the nasal; the second the præ-orbital, the third the orbit, and the lower post-orbital, the fourth and fifth the temporals. The lower rostral is very small, triangular. The seven or eight inferior labials are much smaller than the upper. The two pairs of mentals are very short. The mouth is small; the teeth are very strong, short and of nearly equal size, except the furrowed last upper maxillary tooth and the anterior teeth of the lower jaw, which are longer than the rest. The trunk is robust, back slightly raised in the centre, the sides sloping, their lower half compressed, the abdomen broad, arched. The scales are smooth, rhombic with rounded points, slightly imbricate; those of the sides have the points bent inwards and firmly adhering to the skin, so as to appear hexagonal. On the anterior part of the trunk they are disposed in 27, on the posterior in 25 longitudinal series. The tail is short, robust, tapering and somewhat prehensile. In the male the sides are compressed, very high in the middle; and the lower surface is flattened, very broad, more so than in the posterior part of the abdomen. In the female it is shorter, the sides less high, and the lower surface less broad. The largest male of a considerable number was of the following dimensions:

	Feet.	Inch.
Length of the head,....	0	$0\frac{7}{8}$
Do. do. trunk,.....	1	$10\frac{3}{8}$
Do. do. tail,.....	0	$3\frac{6}{8}$
	2 ft.	$1\frac{7}{8}$ inch.

Circumference of the neck  $1\frac{7}{8}$ , of the trunk  $2\frac{1}{8}$ , of the root of the tail  $1\frac{1}{8}$  inch. With the exception of its colours, the present offers no difference from *H. leucobalia*, from the rivers of Timor. At Pinang it is numerous not only in

## REPTILES OF THE

fresh water and estuaries, but in the sea at some distance from the shore, where it sometimes occurs in fishing nets. It is of sluggish, not fierce habits, and feeds upon fishes and crustacea, aquatic and pelagic. In a young female the oviduct enclosed 4 white cylindrical eggs, which when they were observed contained but yolk; each measured about an inch in length.

(2383g) HOMALOPSIS HYDRINA, N.S. (See Plate, Fig. 4.)

*Adult.*—Ash-coloured above with a few scattered black spots on the neck; the back and tail with numerous transversal black bands; the lips, sides and abdomen uniformly pearl-coloured. Iris ashy; pupil elliptical, vertically contracted by the light; tongue small, whitish.

Scuta 161; Scutella 34.

*Young.*—Resembling the adult, but the ash colour of a much lighter shade.

Scuta 153; Scutella 35.

*Habit.*—Sea off Pinang, and the Malayan Peninsula.

The head is moderately distinct, elongated, depressed, oval with rounded, blunt muzzle; the rostral shield moderate, hexagonal; its lower margin with a central minute tubercle, on each side of which a triangular impression. The upper margin of the minute triangular lower rostral presents a central cavity, and two lateral elevations fitting into the margin of the upper rostral. A similar contrivance in the pelagic serpents enables them hermetically to close the mouth. As in *H. leucobalia*, the single small anterior frontal is elongated hexagonal, broader behind, and enclosed by the rostral, the nasals, and the frontals. Although the nasals are placed laterally, the small arched linear nostrils open vertically, and send a slit to the posterior margin of the shield; the frontals are hexagonal, smaller than the latter; the vertical is the longest of the crown-shields, very narrow, hexagonal, pointed at both extremities, but broader behind; the supra-orbitals are small, narrow; the occipitals are broken up in minor shields: viz. two post-occipitals, in size equal to the occipitals, and a minute conical inter-occipital, enclosed by the four shields, with the broader extremity wedged in between the occipitals. Each temple is covered with two pairs of large shields, of which the lower borders the fifth, sixth, and seventh upper labials. The eye is very minute, prominent, almost vertically placed, surrounded by two post-orbitals, of which the lower is broad pentagonal, meeting beneath the elongated single oblique præ-orbital. Thus none of the upper labials border the orbit. The frenal is moderate, pentagonal. Of the seven upper labials the anterior three pairs are much smaller than the rest

as to make the margin of the lip very bulging in a downward direction. The lower ten or eleven labials are smaller than the upper, except the sixth, which is the largest. The chin with two pairs of shields of which the anterior is very elongated; the throat with numerous minute scales. The mouth is small, the dentition resembles that of *Homalopsis leucobalia*, Var. The trunk would be orbicular, but for the narrow flattened abdomen, the scuta of which are angulated, forming on each side a sharp ridge. The scales are very small, smooth, on the neck disposed in 33, successively in 37, but near the root of the tail in 29 longitudinal series. Those of the back are rhomboidal with rounded points; those of the sides lanceolate with the point bent inwards, so as to appear truncated; each scale leaving a small square interval, in which appears the naked skin. The tail is short, much compressed, tapering and slightly prehensile. In the male the sides are very high, and the lower surface very broad, as noted under *H. leucobalia*, Var. On the broadest part there are as many as 21 longitudinal series of scales. In the female this organ is shorter, the sides less high, and the abdomen less broad.

Of three individuals observed, two were captured in fishing stakes placed in the sea off the shores of Keddah, a third was washed on shore by the waves on the coast adjoining my house at Pinang. The largest male was of the following dimensions:

	Ft.	inch.
Length of the head, . . . . .	0	0 $\frac{5}{8}$
Do. do. trunk, . . . . .	1	4 $\frac{4}{8}$
Do. do. tail, . . . . .	0	2 $\frac{2}{8}$
	<hr/> 1 ft. 7 $\frac{3}{8}$	

Circumference of the neck  $\frac{9}{8}$ , of the trunk 1 $\frac{1}{8}$ , of the root of the tail  $\frac{7}{8}$ , of the middle of the tail 1; two eighths from the apex  $\frac{3}{8}$  inch.

It moved actively and without difficulty on the sand, and did not offer to bite. In one examined the stomach contained remains of two small pelagic fishes. In general appearance and colours the present is more closely allied to the pelagic serpents than any other known species. Whether it exclusively inhabits the sea, or, like *Homalopsis rhynchops*, *enhydrus*, and *leucobalia*, as an occasional visitor, must be a matter of future investigation.—*Journal of the Asiatic Society of Bengal*, page from 897 to 952.

### VENOMOUS SERPENTS.

SUB-FAM. BUNGARINÆ, Bonaparte.

### TERRESTRIAL.

(2384) Gen. ELAPS, Schneider.

# MALAYAN PENINSULA AND ISLANDS.

ble; mouth and eyes small, trunk elongated, throughout of nearly equal circumference, very smooth; tail short, tapering, beneath with scutella.

(2385) *ELAPS MELANURUS*, (Shaw.) See Plate XL, Fig. 6.)

Russell I. Pl. 8. (young).

*Coluber melanurus*, Shaw (young).

*Vipera trimaculata*, Daudin, (young).

*Elaps trimaculatus*, { Wagler } (Young.)  
Merrem, apud { Schlegel }

Strongly iridescent light bay above; from the muzzle a longitudinal black band, joining on the neck a broader transversal black band with whitish edges; a short oblique black line behind the eye, and a similar from the nostril to the middle of the upper-lip; on each side of the anterior part of the back a series of distant black dots; a broad black transversal band with whitish edges, at the root of the tail; a second similar, at a short distance from the apex; lips, throat and the anterior part of the abdomen iridescent yellowish white, changing to yellow or orange on the posterior part; the tail beneath bluish white, with large irregular black spots. Iris black; pupil circular; tongue black.

Scuta 205 to 247; Scutella 24 to 32.

*Habit.*—*Malayan Peninsula*: Tenasserim, Nerva, (Coromandel.)

In general appearance this species nearest approaches *Elaps intestinalis*, (Laurenti), but the eye is comparatively larger, while the nearly equilateral, hexagonal, vertical shield is smaller in the present. The eye is surrounded by two post-orbitals, one præ-orbital, and beneath by the third and fourth upper labials. Of the latter seven pairs cover the jaws. The trunk is throughout covered by 13 series of smooth, sub-imbricate, rhombic scales. The one described by Russell, hitherto the only describer from nature, was a young animal. A similar, upwards of a foot in length, was killed in Province Wellesley. But the late Mr. Griffith in one of his botanical excursions, captured an individual of the following dimensions:

	Feet.	Inch.
Length of the head,.....	0	0 $\frac{5}{8}$
Do. do trunk,.....	1	10 $\frac{3}{8}$
Do. do tail,.....	0	1 $\frac{4}{8}$
	2 ft.	0 $\frac{3}{8}$ in.

Circumference of the trunk 1 inch.

(2386) *ELAPS INTESTINALIS*,\* (Laurenti,) Var.

\* *Note.* Syn. Sebaii, Pl. 2, Fig. 7.—*Aspis intestinalis*, Laurenti—*Coluber intestinalis*, Gmelin.—Russell II, Pl. 19.—*Elaps furcatus*, Schneider.—*Coluber intestinalis*, Shaw.—*Vipera furcata*, Daudin—*Elaps furcatus*, Schneider, apud Wagler, Schlegel.

*Habit.*—Java, Malwah (Central India)

Grant obtained from Saugor, Malwah, contained a single specimen.

Syn.—*Maticora lineata*, Gray: Ill. Ind. Zool.  
*Elaps furcatus*, Schneider, Var. apud Schlegel, Cantor.

*Young and Adult.*—Head above light chestnut; lips and throat yellowish white, upper lips spotted with black; from the hind head to the tip of the tail a vermilion line, on each side of which a narrow, serrated, black line. On the nearest two longitudinal series of scales the ground colour appears as a reddish light grey longitudinal line, beneath bordered by an equally broad black line, under which a narrow buff-coloured line, bordered by a black serrated line, the teeth of which are directed downwards, wedged in between the lateral margins of the scuta and scutella. Scuta alternately pale citrine and iridescent black, the latter colour occupying three to four scuta together, while the former rarely appears on more than two. Tail above with two or three distant black transversal bands; beneath vermilion, with a continuation of the superior transversal bands. Iris black, pupil circular; tongue black.

Scuta 223 to 238; Scutella 24 to 26.

*Habit.*—*Pinang, Singapore, Malayan Peninsula.* Sumatra.

Excepting the colours, this variety otherwise perfectly agrees with *E. intestinalis*. The neck is covered by 15, the rest of the trunk by 13 longitudinal series of smooth, not imbricate rhombic scales. It is of no uncommon occurrence in the hills of Pinang, at Malacca, and at Singapore. The largest individual was of the following dimensions:

	Ft.	Inch.
Length of the head,.....	0	0 $\frac{3}{8}$
Do do trunk,.....	1	10
Do do tail,.....	0	1 $\frac{4}{8}$
	1 ft.	11 $\frac{7}{8}$ inch.

Circumference of the trunk 1 $\frac{3}{8}$  inch.

(2387) *ELAPS NIGROMACULATUS*, Cantor. (See Plate XL, Figure 7.)

Syn.—*Calliophis gracilis*, Gray: Ill. Ind. Zool. (Young).

“Probablement nouvelle espece d’*Elaps*,” Schlegel: Essay, p. 451 (1).

*Elaps nigromaculatus*, Cantor: Spicil.

Head above yellowish brown, each shield with a pale black spot in the middle; lips and throat yellowish white, spotted with pale black. Ground colour of the trunk and tail reddish light grey, longitudinally divided by a central black line with small round, black, white edged spots about an inch apart; on each side two parallel black lines, the lower of which bordering the two lowest series of scales of the sides, which are white edged with black, so as to appear longitudinally

# REPTILES OF THE

black and white lines are on each side intersected by a series of large rounded (the anterior pair elongated), black spots with white edges, placed in pairs, opposite each other, but in quincunx order with the smaller black spots of the dorsal line. Beneath alternately yellowish white or pale citrine, and iridescent black, both colours nearly equally divided. Tail at the root, and near the apex with a broad transversal black band, edged with white, both continued on the vermilion lower surface, and there, between them, a third similar band. Iris black, pupil round; tongue bluish grey.

*Young*.—Marked like the adult, but the ground colour of the back and tail inclines to light reddish brown.

Scuta 238 to 311; Scutella 21 to 28.

*Habit*.—Pinang, Singapore.

In general appearance this species very closely resembles *Elaps intestinalis*, from which it is distinguished by the following characters. [The (magnified?) representation of the head of "*Calliophis gracilis*," Fig. 2. *Ind. Zool.*, is in every particular incorrect.] The two pairs of frontal shields are remarkably disproportionate, the frontals (proper) being much the larger: next to the occipitals they are the largest of the crown-shields. The nearly equilateral, hexagonal vertical, and the supra-orbitals are remarkably small: more so than in any other species of this genus. The occipitals are very narrow elongated; their external margin bordered by two pairs of shields of which the anterior, the larger, cover the temples, and is beneath bounded by the fifth and sixth upper labials. The eye is sunk, excessively minute, surrounded by two small post-orbitals; beneath by the third and fourth upper labials, and by a single narrow triangular præ-orbital. The latter is placed obliquely, so that the downwards pointed apex meets the linear posterior part of the nasal, or as it is considered by some, the frenal. The nostrils are comparatively large. The upper labials number six on each side: the two posterior are the largest. The chin is covered by two pairs of elongated narrow shields, externally bordered by the third and fourth, the largest of the six inferior labials. The gular scales are more numerous than those of *E. intestinalis*. The neck is covered by 15, the trunk by 13 longitudinal series of smooth rhombic scales with rounded points. • This species is of no uncommon occurrence in the hills of Pinang. The largest individual was of the following dimensions:

	Feet.	Inch.
Length of the head,.....	0	0 $\frac{3}{8}$
Do. do. trunk,.....	2	1 $\frac{3}{8}$
Do. do. tail,.....	0	1 $\frac{3}{8}$

2 ft. 3  $\frac{3}{8}$  inch.

Circumference of the trunk, 1 inch.

(2388) *ELAPS BIVIRGATUS*, Kuhl, VAR.

[Syn.—*Erpetologie de Java*, Pl. 44.—*Elaps bivirgatus*, apud Schlegel.]

*Habit*.—Java, Sumatra.

Syn.—*Elaps flaviceps*, Cantor, Spicil.

*Elaps flaviceps*, apud J. Reinhardt: Beskrivelse, &c.

Head, lips and throat vermilion; trunk above brilliant iridescent, intense black, most of the scales partially edged with azure, not however sufficiently to produce regular network; the two lowest series of scales on each side azure, forming a continued lateral band, longitudinally divided by a white zig-zag line, produced by the scales being partially edged with white. Beneath vermilion; each scutum with two lateral, square black spots, forming a continued black band bordering the azure. Tail above with a narrow black dorsal line; sides and scutella vermilion. Iris and tongue black.

Scuta 248 to 277; Scutella 38 to 45.

*Habit*.—Pinang, Malayan Peninsula.

In colours the young ones resemble the adult. The neck is covered by 15, the trunk by 13 longitudinal series of smooth rhomboidal scales. The anterior part of larynx, instead of adhering to the upper part of the membranous sheath enclosing the tongue, presents the peculiarity of being free and projecting in the mouth like a small tube.

Of four individuals observed, the three were from the hills of Pinang. The largest was of the following dimensions:

	Feet.	Inch.
Length of the head,.....	0	0 $\frac{3}{8}$
Do. do. trunk,.....	2	7 $\frac{6}{8}$
Do. do. tail,.....	0	3 $\frac{3}{8}$

2 ft. 11  $\frac{5}{8}$  in.

Circumference of the trunk, 1  $\frac{3}{8}$  inch.

*Elaps intestinalis*, Var, *E. nigromaculatus*, and *bivirgatus*, Var, appear at Pinang, exclusively to inhabit the hills at a considerable elevation, but on the Malayan peninsula, and at Singapore they occur in the valleys. Although not numerous, they cannot be said to be of rare occurrence. They are strictly terrestrial, and have their hiding places under the roots of trees, and in the crevices of rocks. They are sluggish, awkwardly dragging their long slender bodies, and they are generally observed lying motionless, with the body thrown in many irregular folds, but not coiled. Although they are diurnal, their sight from the minuteness of the pupil, appears to be as defective as their sense of hearing, and they may be closely approached, without apparently their being aware of danger. If touched with a stick, they make a few strenuous efforts to slide away, but they

soon stop, and if further pursued, they make some irregular spasmodic-like movements, but they have not been observed to bite. An adult *Elaps bivirgatus*, Var. was on a single occasion seen to raise the head vertically about two inches from the ground. In captivity they refuse food and water, and die in a short time from inanition. Of a number examined, only one of the latter species had in the stomach the remains of a small serpent, the genus of which could not be determined. M. Schlegel has observed *Calamaria* in the stomach of *Elaps intestinalis*. In the peculiar distribution of colours, in diminutive size, and in habits they resemble the genus *Calamaria*. It is solely the smallness of the mouth which renders the preceding species of *Elaps* harmless to man, as from the following it will be perceived, that their venom is as virulent as that of other venomous Serpents. From the diminutive size of the venomous glands, the quantity of fluid secreted is small: scarcely more than a drop from each. It is a pellucid, colourless fluid slightly reddening litmus paper.

After several unsuccessful attempts to make an adult *Elaps nigromaculatus* spontaneously bite a fowl, the jaws were forcibly closed over a protracted fold of the skin on the inner side of the left thigh of the bird. On account of the small gape, some difficulty was experienced in making the jaws close over the fold of the skin, and, as it appeared doubtful if the fangs had penetrated, the serpent was in a quarter of an hour compelled again to wound the fowl in the skin below the right eye. Twenty minutes after the first wound the fowl became purged, and manifested symptoms of pain in the left thigh, which was continually drawn up towards the body, although the wounds inflicted there, and below the eye, were, from the smallness of the fangs, barely visible. Twenty-eight minutes after the first wound the bird commenced drooping, occasionally attempting to raise itself, and in 10 minutes more soporism occurred, interrupted by spasms of the neck, flow of saliva, and pecking the earth with the beak, while the pupil was spasmodically contracted, and alternately dilated. The latter symptoms continued during thirty minutes, when death occurred in an hour after the first wound had been inflicted. Fowls wounded by *Elaps furcatus*, Var, and *Elaps bivirgatus* Var, expired under similar symptoms, from within an hour and twenty minutes, to upwards of three hours. The serpents which all had forcibly to be made to inflict the wounds, shortly afterwards expired, apparently from the violence to which they had been subjected.

(2389) Gen. BUNGARUS, Daudin.

Body elongated, slightly cylindrical; tail short; head oval, trunk and tail with a dorsal series of large hexagonal scales; the tail beneath

with scuta, in the middle sometimes with scutella; behind the fangs some simple maxillary teeth.

(2390) BUNGARUS FLAVICEPS, J. Reinhardt. Young.—Head and neck blood-red, with a pointed elongated black mark between the occipitals, and a short black dorsal line on the neck; the trunk black with steel-blue reflections, at the anterior part of each dorsal hexagonal scale a short longitudinal white streak; near the tail blood-red; each scale of the two lowest lateral series, white with a black spot, placed so as to produce a continued lateral, white zig-zag line; the posterior part of the sides blood-red. Lips and throat blood-red; abdomen black, posterior part as well as the tail blood-red, with a few black spots. Iris and tongue black.

Scuta abdominalia 209; Scuta subcaudalia 16; Scutella 38.

Habit.—Pinang. Java.

M. J. Reinhardt has described the adult from an unique specimen in the Royal Museum, Copenhagen. Spirits of wine change the brilliant blood-red to a pale yellow colour. The diagnosis must therefore be altered accordingly. The adult appears to differ from the young, in having none of the black marks of the head and tail, and no lateral white line.

A single young individual, found by Sir William Norris, on the Great Hill of Pinang, was of the following dimensions:

	Feet.	Inch.
Length of the head,....	0	0 $\frac{5}{8}$
Do do trunk,...	1	4 $\frac{2}{8}$
Do do tail,.....	0	3
	—	—
	1	8 $\frac{1}{8}$

Circumference of the neck 1, of the trunk 1  $\frac{2}{8}$ , of the root of the tail  $\frac{5}{8}$  inch.

The centre of the back forms a ridge, from whence the sides slope; the abdomen is broad, slightly arched, so that the vertical section of the body becomes broad triangular. The neck is covered by 15, the trunk by 13 longitudinal series of smooth, imbricate, rhomboidal scales. As observed by M. J. Reinhardt, the correspondence of colours, and their distribution, between this species and *Elaps bivirgatus* is very striking. Besides, the number of series of scales, is another character, approximating this species to the genus *Elaps*.

(2391) BUNGARUS CANDIDUS, (Linne.)

SYN.—Seba II, T, 66, Figs. 3 and 4.

Coluber candidus, Linne.

Russell I, Pl. 1. Paragoodoo.

Russell II, Pl. 31, Sew Walaley.

Pseudoboa coerulca, Schneider.

Boa lineata, Shaw,

Bungarus coeruleus, Daudin.

Bungarus semifasciatus, Kuhl.

Aspidoclonion semifasciatum, Wagler.

Bungarus semifasciatus, Schlegel.

## REPTILES OF THE

Above black with steel blue reflections, interrupted by numerous narrow transversal white bands, produced by the white edges of the scales. On each side the bands are bifurcated, and the two or three lowest series of scales, white with black spots. Lips and throat white; abdominal surface yellowish white. Iris black: tongue white.

Scuta 201 to 221; Scuta subcaudalia 38 to 56.

*Habit.*—*Malayan Peninsula*. Java, Tenasserim, Bengal, Assam, Coromandel, Ceylon, Malabar.

A single young individual, killed by Capt. Congalton near Keddah, was of the following dimensions:

	Feet.	Inch.
Length of the head,...	0	1
Do. do. trunk,...	2	3 $\frac{5}{8}$
Do. do. tail,....	0	4 $\frac{5}{8}$
	—	—
	2	9 $\frac{3}{8}$

Circumference of the neck 1  $\frac{1}{8}$ , of the trunk 2, of the root of the tail 1  $\frac{1}{8}$  inch.

Assam produces also a constant variety (*B. lividus*, Cantor) of a uniform blue black above; beneath yellowish white: in some the scuta blackish with white edges. In the very young the head is white with a black line between the occipital shields. It further differs in having the hexagonal scales smaller, less distinct from the rest, and the tail more robust than the normal individuals.

(2392) *BUNGARUS FASCIATUS*, (*Schneider*.)

*SYN.*—Scheuchzer, Pl. 655, Fig. 8.

Seba II, Pl. 58, Fig. 2.

Russell, I, Pl. 3, Bungarum Pamab.

*Pseudoboa fasciata*, Schneider.

*Boa fasciata*, Shaw.

*Bungarus annularis*, Daudin.

*Aspidoclonion*, Wagler.

*Bungarus annularis*, Schlegel.

Ground colour bright gamboge; the anterior half of the head, and the cheeks black with steel blue reflection; from the vertical shield a black longitudinal band, expanding over the neck and sides, and with the former forming a broad arrow mark; lips and throat gamboge, upper lips edged with black; the rest of the body completely surrounded by a number of broad, alternate gamboge and shining black, rings. Iris black; tongue flesh-coloured.

Scuta 200 to 234, scuta abdominalia 32 to 36.

*Habit.*—*Pinang, Malayan Peninsula*. Java, Tenasserim, Bengal, Coromandel.

The neck is covered by 17, the trunk by 15 longitudinal series of smooth scales, which with the exception of the dorsal hexagonal series, are imbricate, rhombic. As noted under *Elaps bivirgatus*, *Var*, the larynx is not attached to the scabbard of the tongue. Of three young individuals from the valley of Pinang and Province

Wellesley, the largest was of the following dimensions:

	Feet.	Inch.
Length of the head,....	0	1 $\frac{3}{8}$
Do. do. trunk,...	3	5
Do. do. tail,.....	0	4 $\frac{1}{8}$
	—	—
	3	10 $\frac{3}{8}$

Circumference of the neck 2, of the trunk 3  $\frac{3}{8}$ , of the root of the tail 2, of the apex 1  $\frac{3}{8}$  inch.

In the Malayan countries the species of *Bungarus* are not numerous, but *B. Candidus*, and *fasciatus* are of no uncommon occurrence in Bengal and on the Coromandel Coast, where, however, it should be observed, a class of the natives ("serpent-charmers,") earn a livelihood by capturing and exhibiting serpents, but this craft is unknown among the Malays.

The preceding three species, like the rest of the venomous serpents, are very ferocious when attacked, but unprovokedly they are not known to attack man: on the contrary, when met in the jungle, they attempt to escape. When trod upon, or struck, their rage is instantly excited, in self-defence they will even turn from their retreat, and then their habitual sluggishness is roused to furious activity. Preparing to attack, the head is, by a short curve of the neck, brought closely to the body, and drawn far backwards, when suddenly darting the anterior part of the body obliquely upwards, they bite. The height of the place where the wound is inflicted, of course depends on the length of the serpent, which is capable of darting nearly the anterior half of the body. Notwithstanding the circular pupil, they appear to shun the light, hiding the head under the folds of the body, and they are singularly uncertain in their movements, often suddenly jerking the head or tail without any apparent object. Like all serpents of tropical Asia, they seldom expose themselves to the sun: when during the day they leave their hiding places, they select the shade. The genus *Bungarus* is terrestrial, feeding on rats, mice, serpents, (*Col. mucosus*, Lin) and toads. Like other venomous serpents, when the venom has been inflicted on their prey, they disengage it from the fangs, sheathe and place them as horizontally as possible, in order that they may offer no resistance to the introduction into the mouth of the lifeless prey, which is now seized head foremost. The innocuous serpents bite or strangle their prey, which when life is extinct is either swallowed at once, or if it happens to have been killed in a position, likely to render the deglutition difficult, is often disengaged from between the teeth, and seized a second time, by the head. In captivity these serpents refuse food, but greedily lap up and swallow water.

A fowl four minutes after it had been bitten on the inner side of the thigh, by a *Bungarus*

# MALAYAN PENINSULA AND ISLANDS.

*fasciatus*, fell on the wounded side, and was shortly after seized with slight purging. The eyes were half closed, the pupils alternately dilated and contracted, immobile. In 17 minutes slight spasms occurred, under which the bird expired 43 minutes after it had been wounded.

\* Another few wounded in the same place as the former, by the same serpent, but after an interval of seven hours, expired under similar symptoms, only more violent spasms, in the course of 23 minutes.

Venom taken from another serpent, the fangs of which had been extracted, was inoculated by a lancet-incision in the right thigh; four minutes after the fowl was seized with trembling, fell, and remained lying on the wounded side, with the eyes closed, but it gradually recovered, and rose apparently recovered, 30 minutes after the inoculation of the venom.

Other fowls were killed by different serpents of this species, in 20 to 31 minutes.

Fowls bitten by *Bungarus candidus* expired under similar symptoms, within 30 to 45 minutes; dogs from within 1 hour 10 minutes, to 2 hours, under symptoms noted in Russell's experiments (Russell I, page 53.)

SUB-FAM. NAJINÆ, Bonaparte.

(2393) HAMADRYAS, Cantor.

Head broad, sub-ovate, depressed, with a pair of very large post-occipital shields, and a short, blunt muzzle; cheeks tumid; eyes large, prominent, pupil circular; nostrils wide, between two shields; behind the fangs a few maxillary teeth; neck dilatable; trunk thick, cylindrical; tail short, with Scuta and Scutella.

(2394) HAMADRYAS OPHIOPHAGUS, Cantor.

SYN.—Hamadryas hannah, Cantor.

*Naja elaps*, Schlegel, (Young.)

*Naja bungarus*, Schlegel, (Young)

*Naja vittata*, Elliot.

*Hamadryas ophiophagus*, apud. Elliot, b

Olive green above; the shields of the head, the scales of the neck, posterior part of the body, and of the tail edged with black; the trunk with a number of distant, oblique, alternate black and white bands, converging towards the head; the throat and anterior part of abdomen impure gamboge, the rest of the scuta and scutella bluish gray; marbled with black, or pale yellowish green, with a narrow submarginal brown line. Iris golden, spotted with black; tongue bluish black.

Scuta 215 to 256; Scuta sub-caudalia 13 to 32; Scutella sub-caudalia 63 to 96.

*Habit.*—Pinang, Singapore, Malayan Peninsula, Java, Sumatra, [Note. Sir Stamford Raffles' specimen in the Museum of the Zoological Society, London.] Bengal, Assam, [Specimen in the collection of H. Walker, Esq. Surgeon, G. G.] Coromandel.

Of two individuals, from the summit of the

Great Hill of Pinang, and from Province Wellesley, the larger was of the following dimensions:

	Feet.	Inch.
Length of the head,...	0	3
Do. do. trunk,...	8	1
Do. do. tail,....	2	4
	10	8

Circumference of the neck  $5\frac{2}{3}$  of the trunk  $8\frac{5}{8}$ , of the tail,  $4\frac{1}{8}$  inch.

The neck is covered by 21, the trunk by 17 longitudinal series of smooth imbricate scales; those of the two lowest series are large rhombic; of the sides irregular rhomboidal, appearing linear, all with rounded apex. The Malayan individuals are of a lighter colour, more inclining to yellow, than those observed in Bengal.

(2395) *Gen. NAJA*, Laurenti.

Head covered with shields; muzzle truncated; the anterior part of the trunk, between the 6th and 12th abdominal scutum, considerably dilatable in the shape of a disk, with a large, white, transparent spot above, edged with black, and somewhat resembling a pair of spectacles.

(2396) *NAJA LUTESCENS*. \* Laurenti, Var. (D. Daudin.)

SYN.—Seba II, T, 97, F, 4,

*Naja peruviana*, Lacepede.

Russell, I, Pl. 5, Fig. 4, Sankoo Nagoo.

Latreille IV. T. 27.

*Vikera naja*, Var D, Daudin.

*Aspis*, Wagler.

*Naja tripudians*, Var, Gray, Ill, Ind. Zool.

*Naja tripudians*, Merrem, Var, Schlegel.

"Ular mata-ari." of the Malays.

\* [Note.—*Coluber naja* Linne *Naja lutescens*, Laurenti, the *Cobra de Capello*, has probably the widest range of the Asiatic venomous serpents. The species, or its varieties, inhabits the countries between the Sutlej and Cape Comorin, and Ceylon. According to Mr. Hodgson's observations it does not occur in the valley of Nepal, but it ranges through Hindustan down to Cape Romania, the southern extremity of the Malaya Peninsula, and from thence to Chusan, 30° N. E. 122° E. It is also found in the Philippines, Ternate, Borneo, Java, Sumatra.]

Head shining dark brown above; on the sides and lips brownish white; ground colour of the trunk buff, the anterior half of each scale pale greyish brown; beneath buff. Iris black with a narrow light grey margin towards the orbit; tongue light flesh-coloured.

*Young.*—Much lighter brown than the adult and strongly iridescent.

Scuta 189 to 193; Scutella 49 to 54.

*Habit.*—Pinang, Singapore, Malayan Peninsula, Bengal, Coromandel.

It is numerous in the Malayan hills and valleys, but apparently of uncommon occurrence in Bengal.

# REPTILES OF THE

(2397) VAR. *NAJA NIGRA*.

*Syn.*—*Naja tripudians*, Var. *nigra*, Gray, Illustr. Ind. Zool.

*Naja tripudians*, Var. Schlegel.

Upper parts intense black with strong purple or blue reflections. temples, lips, and throat pale orange, largely spotted with black; the lateral part of the anterior eight or ten, and of the 14th, 15th and 17th scuta pale orange, black in the centre and with a broad black margin; the scales and interstitial skin on each side of the anterior eighteen or twenty scuta white or buff, appearing on the lower surface of the hood as two short parallel bands. The rest of the abdominal surface paler black than above, strongly iridescent, in certain lights pale silvery. Iris black with the lorbita margin pale gray; tongue light flesh coloured.

Scuta 184 to 187; Scutella 49 to 52.

*Habit.*—*Pinang, Singapore.*

At Pinang the preceding variety prevails, at Singapore the present. Both are local, and they appear respectively to congregate on single spots of limited extent.

Another black variety (*Naja atra*, Cantor) which inhabits Chusan, differs from the present in having a number of distant transversal double lines of a yellow colour. Beneath it is slate or pearl-coloured.

The food of *Naja lutescens* consists of rats, small birds, (it occasionally ascends trees,) lizards, and fishes, in search of which latter it frequently takes the water, and even the sea, along the coasts. The largest individual of the two Malayan varieties, was of the following dimensions:

	Feet.	Inch.
Length of the head,.....	0	1 $\frac{7}{8}$
Do. do. trunk,...	4	1
Do. do. tail,.....	0	9
	4	11 $\frac{7}{8}$

Circumference of the neck, 2 $\frac{7}{8}$ , of the trunk, 4 $\frac{3}{8}$ , of the root of the tail,  $\frac{3}{8}$  inch.

The following Memorandum relative to the venom of *Naja lutescens* (Laurenti) has kindly been communicated by J. M. Laidlay; Esq., Joint Secretary, Asiatic Society.

"The venom was carefully obtained so as to avoid any admixture of saliva, by compressing the venomous glands. It issued from the lower aperture of the fangs in viscid drops of a syrupy consistency, and was received as it fell from the fangs in platina capsules. The serpents operated upon were an adult *Cobra de Capello* (*Naja lutescens*, Laurenti) and one of its varieties (*Naja Kaouthia*, apud Belanger) and were supplied by the kindness of J. W. Grant Esq. C. S."

"In every instance the venom readily changed the blue of litmus to red, and restored the bright yellow to turmeric paper that had been reddened by the application of caustic alkali; an unequivocal

proof of acidity. When left to spontaneous evaporation, it dried into a varnish resembling mucilage, or the glare of an egg, cracking in all directions; and on being heated it deposited an abundant coagulum, apparently albuminous. In either instance when redissolved, it retained its acid property."

"What the nature of this acid may be, it was impossible to determine from the small quantity operated upon; nor am I prepared to say that the poison itself is an acid, although if it be not so, it is certainly associated with one. Most probably from the rapid and spontaneous disappearance of its properties by keeping, the poison itself consists of some exceedingly unstable compound, which would be wholly disorganised, under any attempt at solution by chemical means."

SUB-FAM. VIPERINÆ, Bonaparte.

(2398) Gen. TRIGONOCEPHALUS, Oppel.

Head broad triangular, scaly, with a pit before the eyes; trunk robust, cylindrical, tail short, tapering to a point, with scutella beneath.

(2399) TRIGONOCEPHALUS GRAMINEUS, (Shaw)

SYN.—Russell, I. Pl. 9, Bodroo Pam; II. Pl. 20. Coluber gramineus, Shaw.

Vipera viridis, Daudin.

Trimeresurus viridis, Lacepede.

Cophias viridis, Merrem.

Coluber gramineus, apud Raffles; Tr. Linn. Soc. XII.

Bodroo Pam. Russel, apud Davy: Ceylon &c. Bothrops, Wagler.

Trigonocephalus viridis, schlegel.

Trigonocephalus erythrurus, Cantor(young)

"Ular daun" of the Malays.

Grass green above, lighter on the sides, frequently interrupted by zig-zag lines, produced by the black interstitial skin; the tail in some bright cinnamon-red; from the sides of the neck along the lowest series of scales a pale yellow line. Lips, throat and abdominal surface greenish yellow; scutella in some spotted with cinnamon-colour. Iris golden, dotted with brown, but leaving a narrow margin bordering the elliptical black pupil, which is vertically contracted by the light. Tongue pale bluish with black apex.

Scuta 165 to 170; Scutella 58 to 71.

*Habit.*—*Pinang, Singapore, Malayan Peninsula.* New-Holland, [Note. Lacépède, on the authority of M. Baudin.] Timor, Pulo Samao, Celebes, Eastern Java, Banka, Sumatra, Tenasserim, Bengal, Chirra Punji, Nipal, [Note. Specimen in Mr. Hodgson's collection.] Coromandel, Ceylon.

VAR.

(2400) *Coluber graminens*, Var. apud Raffles, l.c.

Differs from the preceding by its Indian or brick-red line on each side.

*Habit.*—*Pinang, Singapore, Malayan Peninsula.* Sumatra, Tenasserim.

# MALAYAN PENINSULA AND ISLANDS.

In the *Malayan* hills and valleys the variety is by far the more numerous : it is indeed the most common of the venomous serpents. In Bengal I never observed but a single one, (*T. erythrus*), captured in the Sunderbuns. It is generally observed on trees, hanging down from the branches, or concealed under the dense foliage ; it preys on small birds and tree-frogs [*Polydectes leucomystax*, (Gravenhorst.)] But occasionally it descends to the ground, in search of frogs and toads. The neck is covered by 27 ; the trunk by 23 or 25 ovate imbricate, keeled scales. The tail is prehensile.

Of a number examined none exceeded the following dimensions :

	Feet.	Inch.
Length of the head,...	0	$1\frac{4}{8}$
Do. do. trunk,...	2	0
Do. do. tail,....	0	$5\frac{6}{8}$
	—	—
	2	$7\frac{2}{8}$

Circumference of the neck  $1\frac{4}{8}$ , of the trunk  $2\frac{2}{8}$ , of the root of the tail 1 inch.

(2401) *TRIGONOCEPHALUS SUMATRANUS*, (Raffles)\* *Var.* (See pl. XL, Fig. 9).

*Syn.*—"Ular kapak" of the Malays of the Peninsula.

\* [*Syn.*—Seba, II. T. 68, F. 4.—*Coluber sumatranus*, Raffles, Ular Poochook.—*Cophias Wagleri*, H. Boie.—*Tropidolaemus*, Wagler.—*Trigonocephalus wagleri*, Schlegel.]

*Habit.*—Sumatra.

*Young.*—Grass green above lighter on the sides and lips ; from the pit beneath the eye, over the cheek a cinnamon red line with the upper margin buff ; on each side of the back a series of distant spots, half cinnamon, half buff coloured, each of the two or three scales composing the spots, being of these two colours ; on the tail the spots are confluent, forming transversal lines. Beneath light yellowish green. The largest individual in this garb measured 1 ft.  $3\frac{2}{8}$  inch. in length.

*Adult.*—Ground colour above light yellow, or pale greenish yellow, largely mixed with intense dull black, so as to make the general appearance black, through which the ground colour appears on the head as irregular spots, and a continued line, beneath which a black line proceeds from the eye to the occiput : on the trunk and tail a narrow, distant, transversal band, continued or broken up into spots. Labials, gulars, the lowest two or three lateral series of scales, and scuta gamboge with black margins ; scutella largely spotted with black. Iris golden dotted with black and with a black transversal bar, pupil elliptical, vertically contracted by the light ; tongue bluish grey.

Scuta 141 to 147 ; scutella 42 to 52.

*Habit.*—Pinang, Singapore, Malayan Peninsula.

Unfortunately in the Malayan countries this variety is not of so rare occurrence as the species appears to be in Sumatra. Both are equally dreaded. The natives of Sumatra denominate it "Puchuk," a young, green shoot of a tree, a name expressive both of its colour and arborial habits. The Malays of the Peninsula, who only know the black variety, call it from its broad cordate head the "hatchet shaped" serpent, "Kapak," or "Kaph" signifying an axe. At Pinang it generally occupies the lower parts of the hills or the valleys, either on the ground or on trees, but Dr. Montgomerie in one instance observed it at an elevation of 2,200 feet. It preys upon rats, small birds, tree-frogs and toads. The neck is covered by 27, the trunk by 23 to 25 longitudinal series of ovate, imbricate keeled scales. The labials, and the gular scales are sharply keeled, but the keels of the former become obliterated with age. The tail is prehensile. Of nine examined the largest individual was of the following dimensions :

	Feet.	Inch.
Length of the head,.....	0	2
Do. do. trunk,...	1	$6\frac{4}{8}$
Do. do. tail, .....	0	$6\frac{1}{8}$
	—	—
	2	$2\frac{5}{8}$

Circumference of the neck  $2\frac{6}{8}$ , of the trunk  $4\frac{4}{8}$ , of the root of the tail  $1\frac{6}{8}$  inch.

(2402) *TRIGONOCEPHALUS PUNICEUS*, Reinwardt.

*Syn.* Seba. II. Tab. 64 Fig. I.

Klein : Tentam, Pg. 10. No 25. \*

*Vipera acontia* Laurenti.

*Coluber acontia*, Gmelin.

*Vipera acontias*, Daudin.

*Echidna acontia*, Merrem.

*Trigonocephalus puniceus*, Reinwardt.

*Atropos*, Wagler,

*Trigonocephalus purpureo-maculatus*, Gray, Ill.

Ind zool.

*Trigonocephalus puniceus*, Schlegel,

\* [As several serpents have by Klein been indicated under the name of *acontias*, the specific name of Reinwardt has been substituted.]

Dull reddish-brown or olive tinged with purple ; in some an indistinct black line from the eye to the sides of the neck ; the scales dotted or finely marbled with black, their keels pale ochre ; the posterior part of the trunk and tail with irregular dark brown spots ; the interstitial skin reddish brown, lighter or darker than the scales ; lips, throat, the three or four lowest series of scales, and beneath pale greenish yellow ; scuta and scutella with brown margins, the latter largely spotted with brown. Iris greenish golden marbled with black ; pupil elliptical vertically contracted by the light ; tongue light brownish grey.

Scuta 162 to 171 ; Scutella 65 to 70.

## REPTILES OF THE

*Habit.*—*Pinang, Malayan Peninsula.* Singapore, Java.

The Malayan individuals differ slightly from the Javanese in having very few dark spots and no reddish line above the black one on the sides of the head. The oval gular scales have a tubercular appearance. The integuments of the head and body are remarkably lax, like those of *Acrochordus javanicus*. The neck is covered by 31, the trunk by 27 longitudinal series of ovate or conical scales; they are not imbricate, but are frequently surrounded by the naked skin. The tail is prehensile, but less so than in the preceding species. The Malayan individuals appear to be less numerous than the Javanese.

The four observed were all found on the ground in valleys. The largest, which had been feeding on a rat was of the following dimensions;

	Feet:	Inch.
Length of the head, ..	0	1 $\frac{4}{8}$
Do. do. trunk, ..	2	5 $\frac{3}{8}$
Do. do. tail, .....	0	5 $\frac{4}{8}$
	3	0 $\frac{3}{8}$

Circumference of the neck 2, of the trunk 3  $\frac{4}{8}$ , of the root of the tail 1  $\frac{3}{8}$  inch.

In general sluggish, but when roused, ferocious habits, the preceding three species resemble the genus *Bungarus*; their mode of attack is also similar: like *Vipera Russellii*, (Shaw), [Note. SYN.—Russell, I. Pl. 7. *Katuka Rekula Poda*, II. Pl. 32.—*Coluber russellii*, Shaw.—*Vipera elegans*, Daudin.] when it prepares to dart, they vibrate the prehensile tail, and utter a faint hissing sound. As the pupil is vertically contracted by the light, they frequently miss their aim, and like *Bungarus*, *Naja*, *Vipera Russellii* and *Hydrus*, in the extreme of fury, they will fix the fangs in their own bodies. Although they are averse to motion, they are not of quite so stationary habits as represented by M. Schlegel, (*Essay: Partie Descriptive*, page 520.) In the jungle I have noticed them moving between the branches of trees or on the ground, either in search of prey, or after heavy rains have flooded their hiding places. In Bengal most terrestrial serpents keep the latter during the hot season, but the rains send them abroad in search of dry localities. Although the present genus has venomous organs, as highly developed as *Crotalus* or *Vipera*, the effects produced by wounds of two species at least, appear to be less dangerous, than might *a priori* be supposed. According to Russell's experiments with the venom of *Trionocephalus gramineus*, chickens expired within 8 to 33 minutes, pigeons in 14 to 18 minutes. A pig recovered in 6 or 7 hours, a dog in 2 to 3 hours, after having been wounded, (Russell, I. page 60.) Mr. Hodgson has seen a man who was wounded by this

species, the only venomous known to inhabit Nepal, fearfully suffering from pain and swelling, but he never heard of a fatal case.—*Transactions Zoological Society*. London. Vol. II, page 309.

A male *Trionocephalus puniceus*, successively wounded two fowls, one in the chest, the other in the left thigh. In both cases the fangs of both sides acted, but neither of the birds experienced any other effect except a slight pain, which lasted a few minutes after they had been wounded. It should, however, be observed, that the serpent at the time had gorged itself with food, in which state it was observed close to the General Hospital, in the valley of Pinang. Another individual was subsequently caused to wound a fowl on the inside of the thigh. The bird immediately drew up the wound leg, fell down and was purged 3 minutes after being wounded. In 3 minutes more, slight spasms of the head and neck appeared at short intervals, but they ceased in 5 minutes, when the fowl made, at first some unsuccessful, attempts to rise. Twenty-one minutes after having been wounded, the bird rose, shook the wings, and had perfectly recovered. The same serpent subsequently was made to wound another fowl on the inside of the left thigh. The bird drew up the wounded leg, and was slightly purged, but showed no other inconvenience from the wound.

The following experiment is communicated by Dr. Montgomerie. An adult *Trionocephalus sumatranus*, Var. was made to bite a fowl in the fleshy part of the thigh. The bird limped about for a short time, and a minute after it was wounded commenced purging. At the end of two minutes it fell, breathing laboriously and was strongly convulsed. At the end of six minutes a few drops of water exuded from the eyes; in fifteen seconds more it was quite dead: six minutes and a quarter after it had been wounded. Both fangs had acted, the wound was livid, and similar lines were observed in the course of the absorbents. On another occasion, after some unsuccessful attempts to make another individual bite a fowl, a terrier accidentally was wounded in the fleshy part of the fore-arm. The serpent fixed the fangs for an instant in the flesh; the dog pitifully screaming, jumped and shook it off. A ligature was immediately applied above the elbow, and the dog secured in a cage. It continued for some time whining from pain, probably aggravated by the tight ligature, which was removed at the close of half an hour, and the dog let free. In a short time it had regained the free use of the limb and was apparently well. But on the third day following a perfectly circular slough, including the bitten spot of about  $\frac{3}{4}$  of an inch in diameter, was thrown off, the sore readily healed up and the dog suffered no further inconvenience.

## MALAYAN PENINSULA AND ISLANDS.

## PELAGIC.

FAM. HYDRIDÆ, *Bonaparte*.(2403) *Gen. LATICAUDA*, Laurenti.

Tail compressed, with two surfaces, gradually increasing in height, and with three furrows (sutures) on each side.

(2404) *LATICAUDA SCUTATA*, Laurenti.

SYN.—*Coluber laticaudatus*, Linne. Mus. A. Fig. 1754.

*Laticauda imbricata*, Laurenti? 1768.

*Le serpent large queue*, Daubenton, 1748.

*Coluber laticaudatus*, apud Thunberg, 1787.

*Coluber laticaudatus*, apud Gmelin, and E. W. Gray, 1789.

*La queue plate*, Lacepede, 1801.

*Hydrus colubrinus*, Schneider, 1801.

*Platurus fasciatus*, Latreille, 1802.

*Hydrus colubrinus*, apud Shaw, 1802.

*Platurus fasciatus*, Daudin, 1803.

*Aipysurus lævis*, Lacepede, 1804, (Var?)

*Platurus semifasciatus*, Reinwardt, M. S.

*Platurus fasciatus*, apud Wagler, 1830.

*Hydrophis colubrina*, Temminck and Schlegel, Fauna Japonica, Tab. 10.

*Hydrophis colubrina*, Schlegel, 1837.

*New born*.—Ground colour gamboge, greenish above, with numerous distant broad rings of a blue reflecting black colour, encircling the body; the first and second black mark of the head and neck are beneath joined by a short longitudinal line, commencing on the lower labial shields; another shorter black line borders above the gamboge upper labials; the scales between the rings, the scuta and scutella with blackish margins.

*Older*.—Of paler colours, lead-grey on the back; the rings impure light blue on the sides and abdomen. The scales and scuta without blackish margins. Iris black, pupil circular; tongue grey.

Scuta 227 to 246; scutella 32 to 41.

*Habit*.—Sea of the Malayan Peninsula and Islands.

Bay of Bengal (Ramree, Pondicherry, Nicobars), Sea of Timor, Molucca and Liewkiew Islands, Celebes, New Guinea, Tongataboo, China Sea.

This species is readily identified by the abdominal scuta, and the scutellated very broad tail. The anterior frontals are separated by a small elongated pentagonal, or rhombic, shield, bordered behind by the vertical, which is proportionally the largest shield, either equaling or exceeding each of the occipitals. The eyes are comparatively large and prominent, surrounded by two post-orbitals, one præ-orbital, and beneath, by the third and fourth of the seven large upper labials. The lower jaw is covered in front by the restral and the two first labials, the succeeding seven are elongated linear and placed horizontally so as to be hid by

the upper labials, when the mouth is closed. The chin is covered by two pairs of pentagonal shields, between which and the labials appear two or three series of elongated scales. The neck is covered by 25, the anterior part of the trunk by 23, increasing to 25 and again decreasing to 19 longitudinal series of large, smooth scales. The nostrils are small, opening laterally. The tail, though much compressed, presents a broad flat surface beneath, till near the apex, where it becomes two-edged. The largest individual examined was of the following dimensions:

	Feet.	Inch.
Length of the head....	0	1
Do. do. trunk....	3	2
Do. do. tail.....	0	5 $\frac{3}{8}$
	3	8 $\frac{3}{8}$

Circumference of the neck,  $1\frac{7}{8}$ : greatest do. of trunk, 4 inch.

(2405) *Gen. HYDRUS*, Schneider.

Body slender in front, gradually thickening, covered with scales; tail compressed, two-edged.

(2406) *HYDRUS STRIATUS*, (Lacepede.)

SYN.—*Leioselasma striata*, Lacepede, 1804,

*Hydrophis striata*, Temminck and Schlegel: Fauna Japon. Pl. 7.

*Hydrophis Striata*, Schlegel: Essay, 1837.

*Hydrophis striata*, Schlegel, apud Cantor, Tr. Zool. Soc. London, Vol. 11.

[Note. DOUBTFUL SYNONYMY.—*Russell II Pl.*, 9, *Chittul*, 1801, agrees with this species in the following characters: the eyes high, small, orbicular; the trunk round till near the anus, where it becomes compressed; the scales smooth, imbricate, orbicular on the sides; the central abdominal series much larger than in any of the other species, (Russell.) The difference of colours is unimportant as it is liable to variations, not only individually but according to age. Besides, all the species acquire a light bluish appearance about the period when the integuments are to be changed. Russell's description was copied by Daudin, who merely supplied the denomination of *Hydrophis cyanocinctus*, (*Hydrus brugmansii*, Boie, 1827,) upon which Wagler founded his genus *Enhydria*, 1830. According to M. Schlegel, all these are synonymes of *Hydrus nigrocinctus* (Daudin). The only means of deciding the synonymy of this and most of the other species appears to be a close examination of such original specimens, described by Russell and Shaw, which may at present exist in the collection of the British Museum.]

*Adult*!—Crown shields light chestnut; lips and throat pale yellow; ground colour above pale greenish yellow, sides and abdomen buff with numerous distant black transversal bands, becoming indistinct towards the tail and on the sides, where the scales are partially edged or spot-

# REPTILES OF THE

ted with black. The interstitial skin of the back and sides black, of the abdomen buff. Iris dark grey with a buff orbital margin; pupil black minute; tongue buff.

Central abdominal series of larger scales,  $347 + 41$ .

*Habit.*—*Sea of Pinang and Malayan Peninsula.* Sea of Liewkiew Islands, Timor, Sumatra, Bay of Bengal.

The eyes are lateral, sunk, excessively small, of a diameter equally the large almost vertically opening nostrils. The single præ-orbital shield is beneath wedged in between the second and third upper labial. The latter, as well as the fourth and fifth, border the orbit beneath. Of the two post-orbitals the lower is wedged in between the fifth upper labial and the large shield resting upon the sixth upper labial. Above the latter and the seventh, the cheeks are covered by three very large shields. The seven upper labials are large and very high. Of the nine inferior labials the two anterior are the largest, and placed vertically, the succeeding seven are smaller and placed nearly horizontally, so as to become partially hid when the jaws are closed. The chin is covered by the first pair of labials and two pairs of elongated mentals, between which and the inferior labials intervene on each side the second labial, three very large shields, and three smaller. The neck is covered by 37, the anterior part of the trunk by 33, and the thickest by 40 longitudinal series of rhombic scales. In the individuals examined by M. Schlegel, all of less length than my own, the series varied from 31, 29 to 27. The scales are rhombic with rounded apex, each scale with a small central tubercle, or an elevated (keeled) line, which however with age becomes indistinct or obliterated. The central larger abdominal scales are hexagonal, with or without a small tubercle on each side. The anus is covered by three or four excessively large scales. The larger individual of two was of the following dimensions:

	Feet.	Inch.
Length of the head,...	0	$1\frac{5}{8}$
Do. do. trunk,...	5	$6\frac{3}{8}$
Do. do. tail,....	0	$4\frac{6}{8}$
	6	$0\frac{6}{8}$

Circumference of the neck,  $3\frac{3}{8}$ , greatest do. of the trunk,  $4\frac{2}{8}$  inch.

(2407) *HYDRUS NIGROCINCTUS* (Daudin)

*SYN.*—Russell, II Pl. 6. Kerril Pattee, 1801.

[*Doubtful Syn.*—Russell, II. Pl. 13. Kud-dell Nagam, 1801 (*Enhydris gracilis*, Merrem, 1820.) *Hydrus spiralis*, Shaw, 1802]

*Hydrophis nigrocinctus*, Daudin, 1803.

*Hydrophis melanurus*, Wagler, 1828.

*Polydotes annulatus*, Lesson, 1833

*Hydrophis nigrocincta*, Schlegel, 1837.

*Hydrophis nigrocincta*, Schlegel, apud Cantor,

l. c.

*New born.*—Ground colour buff or bluish-white; upper lips and muzzle black, and a transversal band across the hind head, from whence proceeds a triangular or cross mark towards the vertex; gular and inferior labia shields edged and spotted with black; trunk and tail with numerous black transversal bands, either encircling the body, or interrupted on the abdominal ridge, where appear a few indistinct black spots; apex of the tail black. Entire length  $8\frac{1}{8}$  inch.

*Older.*—Greyish green olive above, yellowish on the sides, buff beneath; the bands less intense black, often placed obliquely so as to join each other on the back. Iris grey; pupil circular, black; tongue buff. Central abdominal series of larger scales,  $281 + 41$ ;  $284 + 43$ ;  $289 + 39$ .

*Habit.*—*Sea of Malayan Peninsula, Pinang, Singapore.* Estuaries of the Ganges, Bay of Bengal.

This species greatly resembles *H. striatus* from which it differs in the more compressed general form; the eye though small, is of a larger diameter than the nostril, and it is surrounded by a single post-orbital shield, which beneath is wedged in between the fourth and fifth upper labial, and the præ-orbital between the second and third. The orbit is bordered beneath almost entirely by the fourth upper labial. The sixth upper labial is the largest, in some individuals covering the cheek and bordering above the occipital. Of the seven or eight inferior labials the four anterior are very large, above the third there is one or two small triangular shields; the other three or four posterior labials are very small elongated. There is no horizontal series of labials as in *H. striatus*, and the two elongated pairs of mentals immediately border the labials. The neck is covered by 33, the thickest part of the trunk by 53 longitudinal series of scales. Those examined by M. Schlegel, the length of which exceeds those come under my own observation, had 27, 29 to 31 series of scales. Those of the anterior part of the back are rhomboidal, those of the posterior part rhombic with rounded apex and slightly imbricate; those of the sides hexagonal: all have either a sharply raised keel or a central tubercle, both of which frequently become obliterated. The central series of abdominal scales are a little larger than the rest, frequently divided in two hexagonal, and with a small tubercle on each side, which often becomes indistinct, or obliterated. The anus is covered by 3 or 4 very large, or by a series of small scales.

The largest of six individuals was of the following dimensions:

	Feet.	Inch.
Length of the head,.....	0	$0\frac{6}{8}$
Do. do. trunk,....	2	$0\frac{2}{8}$
Do. do. tail,.....	0	$2\frac{6}{8}$
	2	$3\frac{6}{8}$

# MALAYAN PENINSULA AND ISLANDS.

Circumference of the neck,  $\frac{2}{3}$ ; greatest do. of the trunk, 2 inch.

VAR.? (See Pl. XL. Fig. 8.)

Crown shields olive green with a blackish band from the eyes over the anterior part of the upper lip; the posterior part and the lower lip pale yellow; ground colour of the trunk greenish lead grey above, pale yellow on the sides, beneath buff, with numerous black transversal bands. Iris amber-coloured with the orbital margin dark grey. Central abdominal series of scales  $235 \times 38$ .

It differs from the preceding in the following particulars. The head is proportionally shorter, broader triangular, the muzzle more pointed, and the upper surface from the vertical shield very declivous. The eyes are much larger than the nostrils, with a single præ and post orbital, but bordered beneath by the third and fourth upper labial. The latter, six in number, present nothing abnormal. The lower labials are also six, proportionally larger than in the preceding. The mouth is smaller. The make of the trunk is more robust; the neck is covered by 15, the thickest part of the body by 21 longitudinal series of proportionally much broader hexagonal series, tuberculated on the anterior part of the trunk, on the rest keeled, forming series of sharp, continued ridges. The central abdominal series is at first somewhat larger than the rest, angular, with a small more or less distinct tubercle on each side. A single individual, captured in a fishing stake off Pinang, was of the following dimensions:—

	Ft.	Inch.
Length of the head,.....	0	$0\frac{5}{8}$
Do. do. trunk,.....	1	$6\frac{3}{8}$
Do. do. tail,.....	0	$2\frac{4}{8}$
	1 ft.	$9\frac{4}{8}$

Circumference of the neck,  $1\frac{1}{8}$ ; greatest do. of the trunk  $2\frac{1}{8}$  inch.

(2408) *HYDRUS GRACILIS*, Shaw.

SYN.—Russell, 1, pl. 44, Tatta Pam, 1796, (very young.)

[DOUBTFUL SYN.—*Anguis laticauda*, Linne, *Mus. A. F.* 1754. *Vomer. Monogr. Fig. 2*, 1774, *Hydrus fasciatus*, Schneider, 1801.]

*Hydrus fasciatus*, apud Shaw (Russell, 1. 44, excluding the other Syn) 1802.

*Hydrophis obscurus*, Daudin, 1803.

*Hydrophis*, apud Wagler, 1830,

*Hydrus fasciatus*, apud Guerin: *Iconog Rept.* Pl. 25, I, 1829.

*Pelamis chloris*, Merrem apud Horsfield: *Life of Raffles*, 1830.

*Microcephalus gracilis*, Lesson, 1833,

*Hydrophis gracilis*, Schlegel (Syn, *Anguis xip-*

*hura*, Hermann, *Typhlops*, Merr, Tent, p. 158,) 1837

*Hydrophis gracilis*, Schlegel, apud Cantor, 1. c, Pl 56. (Young).

*New born*.—Head shining intense black; ground colour of the trunk and tail bright gamboge, on the back and sides interrupted by numerous black rings, which above are widened into lozenge shape, narrowed on the sides. Throat and anterior half of abdomen intense black, continued as a more or less distinct line to the black apex of the tail. On the sides the yellow ground colour appears in the shape of oval spots, gradually increasing in depth towards the tail. Entire length, 1 ft. 3 inch.

*Adult*?—Head and back uniformly dark olive or brown, becoming greyish on the posterior half, and very indistinct or obliterated on the sides. In some a pale yellow spot on each side of the hind head, and a third on the frontal shields. The lateral oval spots pale sulphur coloured on the anterior half, pale greenish yellow on the posterior. The black of the lower surface very pale, but distinct. Iris black; tongue buff. Central abdominal series of larger scales,  $454 \times 60$ .

*Habit*.—*Sea of Malayan Peninsula and Islands.* Bay of Bengal, Malabar, Sumatra, Borneo.

In form and number the shields of the head resemble those of *Hydrus nigrocinctus*, so as to afford no distinguishing character. Yet it may be readily distinguished from that and other species by the excessive slenderness of the anterior, cylindrical part of the trunk, which from thence becomes much compressed, gradually increasing in bulk and vertical diameter till towards the tail, where the diameter again decreases. The scales of the cylindrical, anterior part of the trunk are rhomboidal with rounded points and slightly imbricate; the rest are hexagonal. The central abdominal series continued beneath the tail, consists of hexagonal scales, a little larger than the rest, and frequently longitudinally divided. In the very young all the scales are smooth, with age the central abdominal ones acquire a small tubercle on each side, and those of the compressed sides and of the back each a central tubercle. In the largest individuals the central abdominal scales have three longitudinally placed minute tubercles on each side, and the rest of the hexagonal scales three or four similar central tubercles. In the new-born the neck is covered by 32, the bulkiest part of the body by 49 longitudinal series; these parts are covered by 26 and 44 series in the largest individual, which is of the following dimensions:

	Feet.	Inch.
Length of the head,.....	0	$0\frac{5}{8}$
Do. do. trunk,...	3	$2\frac{5}{8}$
Do. do. tail,.....	0	0
	3	$7\frac{4}{8}$

## REPTILES OF THE

Circumference of the neck,  $1\frac{2}{3}$ ; greatest do. of the trunk,  $3\frac{2}{3}$  inch.

(2409) *HYDRUS SCHISTOSUS*, (Daudin)

SYN.—Russell, II, pl. 10, Hoogli Pattee, 1801.

[DOUBTFUL SYN.—*Hydrus Major*, Shaw, 1802.—

*Disteira doliata*, Lacepede, 1804.]

Russell, II, Pl. 11, Valakadyen, 1801.

*Hydrophis schistosus*, Daudin, 1803.

*Hydrus valakadyen*, H. Boie, 1827.

*Disteira russelli*, Fitzinger, 1827.

*Hydrophis*, apud Wagler, 1830.

*Leioselasma schistosa*, Fitzinger, 1827.

*Hydrus*, apud Wagler, 1830

*Hydrophis schistosa*, Schlegel, 1837.

*Hydrophis schistosa* Schlegel, apud Cantor, l. c.

*New-born*.—Head above blackish, or dark brown; back and sides with numerous transversal blackish bands, broad above, narrow on the sides; lips, throat sides and abdomen buff; tail blackish with a few transversal buff bands above. Entire length  $10\frac{2}{3}$  inch.

*Adult?*—Head and back either uniformly pale greenish grey, or with darker transversal bands, becoming more or less indistinct on the sides; lips, throat, sides brownish white or buff; tail uniformly blackish, or greyish olive green. Iris pale amber or greenish-yellow, with a grey orbital margin; pupil black, tongue buff.

Central abdominal series:  $239 + 47$ ;  $242 + 42$ ;  $312 + 58$ .

*Habit*.—Sea of Malayan Peninsula and Islands. Bay of Bengal, Malabar, Sumatra.

The head is elongated conical, the muzzle sloping and the rostral shield beneath terminating in a vertically projecting point, which fits into a corresponding cavity in the lower jaw. The anterior elongated triangular frontal shields are next to the occipitals the largest; the large oval nostrils send a slit towards the external margin of the shields. The eyes are lateral, moderate, surrounded by a præ-orbital, a postorbital, frequently cut in two smaller, and beneath by the fourth upper labial shield. Behind the latter, the lip is covered by three or four horizontally placed small shields, above which appear three large vertically placed shields, of which the last borders the sides of the occipital pair. The lower rostral is remarkably elongated, linear, and hid in a furrow between the first pair of inferior labials. Of the latter the anterior five on each side are much elongated, followed by five or six smaller. The chin is covered with numerous minute scales, and like the rest of the body with very lax skin. In the young ones the neck is covered by 47, the bulkiest part of the body by 57 longitudinal series of smooth, somewhat tubercular scales. Older individuals have these parts covered by 48 and 60 series of hexagonal scales, either with a short keel dividing the anterior half, or a central tu-

bercle. The central, slightly raised, abdominal series commences very far back, from one to three inches behind the chin. The anterior scales are wedge-shaped hexagonal, the posterior are broader, but slightly larger, than the rest, with a small elongated tubercle on each side. The largest individual of a great number, was of the following dimensions:

	Feet.	Inch.
Length of the head,....	0	1
Do. do. trunk,...	3	$1\frac{2}{3}$
Do. do. tail,.....	0	$4\frac{2}{3}$
	3	7

Circumference of the neck,  $2\frac{2}{3}$ ; greatest do. of the trunk, 5 inch.

(2410) *HYDRUS PELAMIDOIDES*, (Schlegel.)

SYN.—*Pelamis carinata*, Cuvier, M. S.

*Hydrophis* (*Disteira doliata*, Lacep) Wagler, 1830.

*Lapemis hardwickii*, Gray, Ill. Ind. Zool. 1832.

*Hydrophis pelamidoides*, Schlegel, 1837.

*Hydrophis pelamidoides*, Temminck and Schlegel, Fauna Japon, Tab. 9.

*Hydrophis pelamidoides*. Schlegel, apud Cantor, l. c.

[DOUBTFUL SYN.—Russell, II. Pl. 12, *Shiddil*. 1801.—*Hydrus curtus*, Shaw. 1802.]

*Young*.—Sulphur coloured, paler on the sides and abdomen; the head largely spotted with blackish, through which the ground colour appears in the form of a rectangle, the two sides of which pass from the hind-head to the orbit, the anterior across the frontals, the posterior over the hind-head; two yellow spots between the nostrils, lips yellow, cheeks and throat blackish; on the back a number of transversal blackish bands to the middle of the sides, broader than the intervening yellow lines; tail black. Entire length  $10\frac{1}{2}$  inch.

*Adult?*—Head uniformly reddish brown above; ground colour greenish yellow, lighter on the sides and beneath, with broad lozenge shaped transversal bands of blackish olive, continued on the anterior half of the tail; posterior half blackish. Iris dark olive; pupil black, tongue buff.

*Habit*.—Sea of Malayan Peninsula and Islands. Bay of Bengal, Sea of Celebes, Molucca Islands, China Sea.

The head is much depressed, not broader than the neck; the muzzle broad, rounded; the rostral shield is large, rectangular pentagonal, broader than high, the lower margin with a central point and a notch on each side. The eyes are moderate, lateral, not prominent, surrounded by a præ-orbital, a post-orbital, and beneath by the third and fourth upper labials. The frenal shield, observed by M. Schlegel, was not present in four individuals, examined in the Straits of Malacca; its existence therefore appears not to be constant;

# MALAYAN PENINSULA AND ISLANDS.

in all *Hydri* the shields of the head are liable to considerable individual variations of form. Of the eight upper labials the posterior three are very small, which is also the case with the posterior five of the nine inferior labials. The two pairs of elongated mentals are outside bordered by the three first inferior labials, inside, by several small scales. In the young the neck is covered by 37, the thickest part of the trunk by 40 longitudinal series of hexagonal, smooth, comparatively small scales. In the older individual these parts are covered by 32, and 37, large hexagonal scales, each with a central tubercle. The lower series of the sides are slightly larger than the rest, and vertically elongated, so as to acquire a rectangular appearance. The central abdominal series is much smaller than the rest. Each scale is either rhombic, and, as represented in the excellent plates of *Fauna Japonica*, hemmed in between four [Note. A somewhat similar disposition is observed in the central dorsal series of the however differently shaped scales of *Xenodermus javanicus*, Rienhardt.] of the two lowest lateral series or they are absent, and their place is occupied by a pair of the former, which are soldered together. In young individuals the central series frequently consists of alternate broad triangular, and very minute rectangular scales; both kinds smaller than the rest. The largest individual of four was of the following dimensions:

	Ft.	Inch.
Length of the head,.....	0	1
Do do trunk,.....	1	8
Do do tail,.....	0	2½

1 ft. 11½ in.

Circumference of the neck, 2½; greatest do. of the trunk, 4 inch.

(2411) *HYDRUS BICOLOR*, Schneider.

Syn.—Seba, II, Tab. 77. Fig 1.

Angvis platyura. \* Linne. 1766.

\* In consequence of the specific name of Linne having been applied by Latreille to a genus (*Platyrus*), that of Schneider, the next different in succession, has been substituted.

Vosmaer: Monogr, Fig. 1. 1774.

Angvis platyuros, apud Gmelin, 1788.

Russell, 1. Pl. 41. Nalla Wahlagillee Pam, 1799.

Lacepede V. Tab. 15, Fig. 2. 1801.

*Hydrus bicolor*, Schneider, 1801.

*Hydrophis platyrus*, Latreille, 1802.

*Hydrus bicolor*, apud Shaw, 1802.

*Pelamis bicolor*, Daudin 1803.

*Pelamys* (*Angvis platyura*, Lin) Wagler 1830.

*Pelamis bicolor*, apud Horsfield, Life of Raf. fies, 1830.

*Pelamis bicolor*, apud Oken, 1836.

*Hydrophis pelamis*, Schlegel, 1837.

*Hydrophis pelamis*, Temminck and Schlegel, *Fauna Japonica*, page 60.

Head and back black (inky), forming a straight line on the sides till towards the posterior part, where it becomes largely undulating, so as

to appear as broad band; lips, throat and sides sulphur coloured, turning into yellowish white or buff on the abdomen [Note. In the individual figured by Russell, the bright yellow colour formed a narrow lateral line, below which the sides and abdomen were of a dusky greenish yellow.] and tail; posterior parts of the sides with some more or less distinct rounded black spots; tail largely banded or spotted with black. Iris pale yellow with a broad black orbital margin; pupil black; tongue buff.

*Habit.*—Sea of Malayan Peninsula. Bay of Bengal, Malabar, Sea of Sumatra, Java, Celebes, Molucca Islands, China Sea (to 27° N. Lat.) Otaheite, Bay of Port Jackson (33° 55' S. Lat.—151° 25' E. Long.)

The head is very elongated, depressed, viewed from above, it presents a striking resemblance to *Herpetodryas oxycephalus* (Reinwardt). The eye is larger than in any other species of *Hydrus*, surrounded by two, three, or even four post-orbitals, one large præ-orbital, and beneath, by the fourth upper labial shield. A frenal shield has been observed in some individuals, but it was absent in that examined in the Straits of Malacca, nor does it exist in the specimens, in the Museum of the Asiatic Society. The neck is covered by 44, the thickest part of the trunk by 52 longitudinal series of small scales. Those of the upper parts are smooth, hexagonal; those of the sides approach the orbicular form, and have in the centre one, two, or three longitudinally placed minute tubercles. Similar tubercles are observed on each sides of the scale, forming the central abdominal series, which is composed either of entire hexagonal scales, a little larger than the rest, or they are longitudinally divided into pairs of smaller pentagonal scales, which have the appearance of being divided by an abdominal suture. A single individual taken in a fishing stake, off the coast of Province Wellesley was of the following dimensions:

	Feet.	Inch.
Length of the head,...	0	1½
Do. do. trunk,...	2	1½
Do. do. tail,.....	0	3½
	2	7½

Circumference of the neck, 2½; greatest do. of the trunk, 3½ inch.

The preceding, comprising all the hitherto known species of pelagic serpents, were observed chiefly at Pinang, among the abundant supply of fishes daily carried to the markets. Of their general habits some account appears in the *Transactions of the Zoological Society, London, Vol. II, p. 303*. One of them, *Hydrus schistosus*, is incredibly numerous in the Bay of Bengal, at Pinang and Singapore, far more so than any known terrestrial serpent. The fishing nets are

## REPTILES OF THE

hardly ever worked, but that one or more are among the contents. The other six species are of rare occurrence at Pinang and Singapore, as will be perceived from the disproportionally small number of each, examined during four years, viz. of *Laticauda scutata* : 3 ; *Hydrus striatus* : 2 ; *nigrocinctus* : 6 ; *gracilis* : 7 ; *pelamidoides* : 4 ; *pelamis* : 1.—Of these *Laticauda scutata* is excessively numerous in Timor, *Hydrus pelamis* in New Guinea, the Molucca Islands, and Otaheite, where the natives use it as an article of food. The remaining species, as far as is known, have been observed nowhere in such overwhelming numbers. Large individuals of every species are very seldom seen, it is the young individuals which frequent the coast, and it appears to be questionable, if even the largest observed are animals arrived at their full size. The large individuals are very ferocious ; the young ones are less so. Fortunately for the fishermen the light blinds these serpents, which when out of their proper element, become very sluggish and soon expire. This accounts for the safety of the class of men, whose daily calling brings them in immediate contact with animals, the wound of which is fatal. The fishermen in the straits of Malacca are aware of their danger, and therefore take care to avoid or destroy these reptiles while landing the fishes. The Malays denominate them "*Ular laut*," i. e. serpents of the sea ; among which, however, the innocuous *Acrochordus granulatus*, (Schneider), is also comprised as an inhabitant of the coasts.

### (BATRACHIA.)

#### FAM. CÆCILIDÆ, BONAPARTE.

(2412) *Gen.* ICHTHYOPHIS, Fitzinger, 1826.  
(*Epicrium*, Wagler, 1828.)

Head depressed, elongated ; muzzle obtuse ; maxillary and palatine teeth slender, pointed and couched backwards ; tongue entire with velvety surface ; eyes distinct, below and a little in front of which a fosset with a minutely tentaculated border ; body subfusiform with numerous close circular folds.

(2413) ICHTHYOPHIS GLUTINOSUS (Linne)  
VAR?

Of a uniform sooty brown, paler on the lower surface. Circular folds 254, of which 8 are caudal.

*Habit.*—Singapore.

The transversal diameter, taken at the occiput, is nearly equal to that of the root of the tail, and but little less than the uniform diameter of the trunk, which is between the 24th and 25th part of the entire length. Compared with a specimen of *Ichthyophis glutinosus* (Linne,) the present is of a more robust make ; the head is shorter, the muzzle blunter, and the transversal distance between the nostrils greater. The apex of the tongue and the arches formed by the teeth are

broader, more rounded. The palatal and upper maxillary teeth are blunter, and appear less recurved. Those of the lower jaw, the largest, present an appearance as if each was composed of two distinct parts : a lower which is vertical, broadly triangular, the posterior margin of which supports the upper part, which is curved backwards, and with rounded apex. The circular folds of the skin are fewer, more distant, and with the exception of the 3 or 4 anterior ones, complete. They are disposed in a manner similar to that of *Ichthyophis glutinosus*. The crowded imbricate scales appear to be of a somewhat rectangular form, less rounded than in *I. glutinosus* : in both their surface presents a minute net work.

The fosset of the upper lip is situated in the centre of a small tubercle. The circumference of the fosset is provided with a very short, minute, membranous tube, which, however, after the animal for some years has been preserved in spirits of wine, can scarcely any longer be distinguished.

Length of the head,...	0 $\frac{3}{4}$ Inch.
Do. do. trunk,...	10 $\frac{1}{8}$
Do. do. tail,.....	0 $\frac{1}{4}$

Entire length,..... 10 $\frac{1}{2}$  Inch.

Circumference of the neck, 1 ; of the trunk, 1 $\frac{2}{3}$  ; of the root of the tail,  $\frac{5}{8}$  inch.

A single individual was observed by Dr. Montgomerie at Singapore in 1843, in whose garden it was turned up with the earth, from about two feet below the surface, and from whom I received the specimen, shortly after it had been killed. Although, as stated, it differs in colours and in other characters from the description given by M.M. Dumeril and Bibron of *Ichthyophis glutinosus* (*Epicrium glutinosum*, Wagler, apud D. and B.) as well as from a specimen 10 $\frac{1}{2}$  inch in length, from Assam, the data appear to me insufficient with certainty to determine, whether the present is a distinct species, or a variety of *Ichthyophis glutinosus*, (Linne.)

#### FAM. RANIDÆ, BONAPARTE.

(2414) *Gen.* RANA, Linne.

Skin smooth, hinder extremities very long, formed for leaping ; toes palmated ; teeth in the upper jaw, and in the palate.

(2415) RANA LESCHENAUATI, Dum. and Bibr.

A line of minute conical tubercles along the sides of the body and across the throat. Above uniformly chocolate-coloured ; beneath and on the inner side of the extremities white, more or less vermiculated with pale brown. Iris narrow golden, rhomboidal, the two lower sides not joining each other, but leaving a small open space between them. Web of the toes orange with purple spots.

## MALAYAN PENINSULA AND ISLANDS.

*Habit.*—*Malayan Peninsula*. Pondicherry, Bengal.

The marbled appearance of the upper parts described by M.M. Dumeril and Bibron, does not exist during life, but is acquired when the frog is immersed in alcohol. The species is apparently not numerous. Of two, the larger was of the following dimensions :

Length of the head,.....	0 $\frac{7}{8}$ inch.
Do. do. trunk,.....	1 $\frac{8}{8}$
Do. do. anterior extremity, ..	1 $\frac{4}{8}$
Do. do. posterior, ..	3 $\frac{8}{8}$

*Rana bengalensis*, Gray, *Illustr. Ind. Zool.* is, perhaps, intended to represent this species.

(2416) *RANA TIGRINA*, Daudin.

SYN.—*Rana tigrina*, Daudin. *Hist. nat. Gren. &c.* p. 64, Pl. 20.

*Rana mugiens*, Daudin. l. c. Pl. 23.

*Rana mugiens*, Latreille. *Hist. Rept. F.* 2. p. 153, Fig. 2.

*Rana tigrina*, Merrem.

*Rana limnocharis*, Boie, MS.

*Rana cancrivora* Boie, MS.

*Rana cancrivora*, Gravenhorst.

*Rana picta*, Gravenhorst.

*Rana Brama*, Lesson.

*Rana rugulosa*, Wiegmann.

*Rana vittigera*, Wiegmann.

*Rana cancrivora*, Tschudi.

*Rana tigrina*, apud Dumeril and Bibron.

"Kodok, Katak, Lancha" of the Malays.

Body and limbs above golden greyish-olive or brown, in some with large rounded black spots, and with a yellow line from the muzzle down the back, and a similar broad band from the side of the muzzle to the loins. Beneath and on the innerside of the limbs white or yellow, with or without black spots. Iris burnished golden, the lower half sometimes black, pupil elliptical rhombic.

*Habit.*—*Malayan Peninsula and Islands*. Coromandel, Bengal, Assam, Tenasserim, Java, Sumatra, Timor, Philippines, Canton Province.

The species is excessively numerous in valleys and hills, after heavy falls of rain, but adult individuals are of comparatively rare occurrence. At night the deep short baying sound denotes its presence. The largest individual measured :

Length of the head,.....	1 $\frac{4}{8}$ Inch.
Do. do. trunk,.....	3 $\frac{4}{8}$
Do. do. anterior extremities, ..	2 $\frac{4}{8}$
Do. do. posterior,.....	7 $\frac{4}{8}$

(2417) *Gen. MEGALOPHRYS*, *Kuhl.*

Head very large, broader than the trunk, depressed ; rostral angle and upper eyelid elongated to a point. Tympanic membrane hidden. Nostrils lateral, below the rostral angle. Mouth enormous ; tongue circular, slightly notched behind. Posterior extremity with a short interdigi- tal membrane.

(2418) *MEGALOPHRYS MONTANA*, Wagler, Var.

Above pale greyish brown, with a small black triangular tubercle on each shoulder, and a similar in the centre of the sacrum. From the sides of the muzzle a black band edged with white, continued round the orbit, and then downwards, obliquely over the dark brown cheeks. Outside of the limbs indistinctly marked with black. On the elbows, knees and heels a large round black spot. Posterior margin of the limbs rose-coloured. Fingers and toes yellowish white with transverse black bands. Palms and soles black. Throat and chest sooty with a large white blotch on each side of the latter. Abdomen and inner side of the limbs sooty, vermiculated, and spotted with white. Iris rich golden brown, with minute black net-work. Pupil vertically rhomboidal.

*Habit.*—*Pinang*

Wagler's short description of *M. montana* is drawn up from a preserved specimen, which apparently is also the case with that communicated in *Erpetologie Generale*. From the latter the present animal differs both in colours and in the following particulars. The muzzle forms a pointed lobe resembling the upper eyelids, but smaller. The nostrils are transversely oval, protected by a membranous valve fixed to their lower margin. The upper eyelids are perfectly smooth. The nearly vertical cheeks are above bordered by an angular ridge terminating near the shoulder ; behind by a short curved ridge, which at the angle of the mouth forms a small pointed lobe. The back is smooth without transversal folds, but bordered on each side by a sharp whitish ridge commencing at the upper eyelid, converging towards the cloacal orifice. On the shoulder, near the triangular tubercle, the ridge is enclosed between two short black lines.

Two males were at different times captured on the Pentland Hills, at an elevation of about 1800 feet. One was found in a dark room, where it was observed remaining motionless during several successive days. Its form and colours caused it at first to be mistaken for a withered leaf. The second was taken on a tree. The iris is vertically contracted by exposure to the light. The male has no vocal sacs. The larger was of the following dimensions :

Length of the head,.....	0 $\frac{7}{8}$ Inch.
Do. do. trunk,.....	1 $\frac{7}{8}$
Do. do. anterior extremities, ..	2
Do. do. posterior,.....	3 $\frac{2}{8}$

FAM. HYLIDÆ.

(2419) *Gen. LIMNODYTES*, [The denomination has with propriety been substituted for the inadmissible *Hyla Rana*, Tschudi.] *Dumeril and Bibron.*

Tongue long, narrowed in front, widened, forked free behind, teeth on the vomer, ferru-

# REPTILES OF THE

two groups, between the internal openings of the nostrils; tympanum distinct; Eustachian tubes middling; four fingers free; toes completely or partially webbed; sub-digital disks slightly dilated; process of the first os cuneiforme blunt, very minute; males with vocal sacs; sacral transversal processes not dilated.

(2420) *LISMNODYTES ERYTHRÆUS*, (Schlegel.)

*Hyla erythræa*, Schlegel.

*Hylarana erythræa* Tschudi.

*Limnodytes erythræus*, Duméril and Bibron.

Back and sides brown or reddish olive; a longitudinal silvery white band from the eye to the loin; a second similar from the nostrils, parallel with the former. Beneath silvery white. The inner side of the extremities spotted and lineated with brown. Iris golden brown; pupil vertically rhomboidal.

*Habit.*—*Malayan Peninsula*. Java, Arracan.

Of three individuals observed, the largest was of the following dimensions:

Length of the head,.....	0 $\frac{7}{8}$ Inch.
Do. do. trunk,.....	1 $\frac{6}{8}$
Do. do. anterior extremities, ..	1 $\frac{6}{8}$
Do. do. posterior,.....	4 $\frac{2}{8}$

(2421) *Gen.* *POLYPEDATES*, *Tschudi*, *apud Duméril and Bibron*.

Terminal joints of the fingers and toes widened into a large disk; fingers slightly webbed at their base; Eustachian tubes large; in other particulars resembling *Limnodytes*.

(2422) *POLYPEDATES LEUCOMYSTAX*, (Gravenhorst.)

*Syn.*—*Hyla maculata*, Gray, *Illust Ind Zool*,

*Hyla leucomystax*, Gravenhorst,

*Polypedates leucomystax*, Tschudi, *apud Dum. and Bibr*,

Upper parts changeable: buff, ashy grey, chocolate brown, tinged with rose or lilac, minutely or largely spotted with black. Upper lips white. A blackish band occupying the sides of the head, from the muzzle to tympanum. Beneath whitish or grey, uniformly, or minutely dotted with black. Posterior surface of the thighs blackish or vermiculated with white. Iris silvery or buff; pupil horizontally rhomboidal.

*Habit.*—*Pinang, Singapore, Malayan Peninsula*. Malabar and Coromandel Coast, Bengal.

This species has the power of changing its colours as above described. Although it inhabits Singapore and the sultry plains of Bengal, it appears not to occur in the valleys at Pinang, but to affect the hills, at an elevation of more than 2000 feet, with a mean annual temperature of about 71°.

Length of the head,.....	0 $\frac{2}{8}$ Inch.
Do do trunk,.....	1 $\frac{6}{8}$
Do do anterior extremities	1 $\frac{6}{8}$
Do do posterior,.....	4 $\frac{2}{8}$

## FAM. BUFONIDÆ, FITZINGER.

(2423) *Gen.* *BUFO*, Laurenti.

Body inflated; skin warty; parotids porous; toes united by a rudimentary membrane; no teeth.

(2424) *BUFO MELANOSTICTUS*, Schneider.

*SYN.*—*Bufo scaber*, Daudin

*Bufo bengalensis*, Daudin.

*Bufo scaber*, Latreille.

*Bufo scaber* Daudin, *Hist. Rept.*

*Bufo bengalensis*, Daudin, *Hist. Rept.*

*Le Crapaud de Bengale*, Lesson.

*Bufo dubia*, Shaw, *apud Gray*, *Illust. Ind. Zool.*

*Bufo carinatus*, Gray, *Illustr. Ind. Zool.*

*Bufo melanostictus*, *apud Gravenhorst*,

*Bufo scaber*, Tschudi.

"Kakong" "Katak puru," of the Malays of the Peninsula.

Above earthy brown, grey or buff, in some marbled with black; lips, parotids, crests of the head, points of the tubercles, and last joints of fingers and toes, sooty, or black. Beneath buff, in some vermiculated with black. Iris golden brown; pupil transversely rhombic.

*Habit.*—*Malayan Peninsula and Islands*. Java, Tenasserim, Bengal, Coromandel.

In the Malayan countries this species swarms in valleys and hills. It has in a slight degree the power of changing its colours, and it utters a chirping, plaintive sound. The largest individual examined, measured:

Length of the head,.....	1 Inch.
Do. do. trunk,.....	3
Do. do. anterior extremities,....	2 $\frac{2}{8}$
Do. do. posterior extremities, ..	4 $\frac{2}{8}$

(2425) *Gen.* *HYLÆDACTYLUS*, Tschudi.

Tongue an oval disk, thick, free only at the lateral margins. Palatal teeth. Eustachian tubes very minute. No parotids. Four free fingers with the terminal joint widened, truncated. Five toes united at the base by a very small membrane, the terminal joint not widened; sole with two soft tubercles between tarsus and metatarsus. Sacral transversal processes forming triangular palettes.

*HYLÆDACTYLUS BIVITTATUS*, N. S.

Upper parts and outside of extremities brownish olive with distant small black spots. Head from the muzzle to the middle of the orbit whitish. A broad whitish band edged with black from the posterior angle of the eye, along each side to the loins. A shorter, oblique, similar band from the posterior angle of the eye. Beneath whitish, vermiculated with brown. The throat of the males black. Iris golden brown; pupil transversely rhombic.

*Habit.*—*Malayan Peninsula*.

From *H. baleatus*. Tschudi, the present species differs both in colours and in the following parti-

## PENINSULA OF INDIA.

culars. The profile from the nose to the coccyx forms a considerable arch, the highest part of which is the centre of the back. The male is provided with a vocal sac, the large openings of which are situated on each side of the tongue, and their presence is easily detected by the laxity of the (black) skin of the throat, which forms a broad transversal fold. Between the small openings of the Eustachian tubes the palate presents a considerable transversal fold of the skin, the free margin of which is fringed, which gives it the appearance of a row of teeth. A similar fold has been observed by M.M. Dumeril and Bibron in the genera *Plectropus*, Dum. and. Bibr. and in *Uperodon*, Dum. and. Bibr. In front of this fold is another smaller, between the orbital protuberances. Behind each of the large internal openings of the nostrils, is an arched bony ridge, which in *H. baleatus* supports a few teeth. In the only individual of the present species examined, the free margin of the ridge is cutting, but without teeth. Over the Symphysis of the lower jaw there is a small pointed process, fitting into a corresponding cavity in the margin of the upper jaw. In this species no less than in *Uperodon marmoratum*, Dum. and Bibr. nearly the whole of the thigh is hidden by the skin of the body, so that the posterior extremities are free but from a little above the knees. This character does not appear to exist in *Hylædactylus baleatus*, as it is not mentioned in the description of that species by M.M. Dumeril and Bibron. On the anterior part of the back appear some indistinct rounded elevations; the rest of the upper parts is smooth. The skin of the throat and abdomen presents numerous transversal wrinkles, and is covered with minute tubercles. The toes are more slender than the fingers, and their last joint, although flattened, is not so broad, as that of the fingers, which is of a somewhat triangular form, truncated in front. In *H. baleatus* the fingers are longer than the toes. In the present species however the longest finger, the third, is nearly one-fourth shorter than the fourth toe.

The only individual which I had an opportunity of examining, after its death, was a male taken in a field near Malacca. It was of the following dimensions :

Length of the head,.....	0 $\frac{3}{4}$ Inch.
Do. do. trunk,.....	2 $\frac{2}{3}$
In a straight line from the muzzle to coccyx, following the arch of the back,.....	3 $\frac{1}{2}$
Length of the anterior extremities	1 $\frac{2}{3}$
Do. do. posterior extremities, following the posterior margin,	2 $\frac{1}{2}$

In the nomenclature adopted in the preceding Catalogue it has been Dr Cantor's wish strictly to adhere to the rules proposed by the Committee of the British Association for the Advancement of Science, published in the *Report of the twelfth*

*Meeting*, Rules with which he regrets he was unacquainted before the publication of the Catalogue of Malayan Mammalia.

Fort William, June 1st, 1847.

*T. elegans*, Schœpf. and Shaw.

*T. geometrica*, apud Hutton, *J. A. S.* VI. 689, and plate XXXVIII.

*Kaynchwa*, H.

*Dasari*, Tambel, Teloog; vulgo *Adavi*, *Moonigadoo*, or Jungle deaf-fellow.

Indian Land Tortoise. Eng.

This Tortoise is tolerably common in the low Jungles of the Carnatic, and throughout the whole of the Peninsula. Length of the shell of one about 6 inches. [Capt. Thos. Hutton gives much larger dimensions *loc. cit. supra*; and we have a specimen which I picked up dead in a street of Calcutta, the length of carapax of which (in a straight line) exceeds 12 inches. Three living specimens which I received from Vizagapatam 5 or 6 years ago, certainly did not grow much in the interim, and the carapax of one of these recently dead, and added to the Society's museum, measures 8 $\frac{1}{2}$  in. It also inhabits Ceylon; but not Lower Bengal.—E. B.]

FAM. ELODIDÆ—Marsh Tortoises.

(2429) *Gen. EMYS*.

[For generic characters, vide Journ. As. Soc. 1847, p. 608. I think it superfluous to repeat in this journal the characters so lately laid down in Dr. Cantor's most admirable Catalogue.]

(2430) EMYS TRIJUGA, Schw.

SYN. *E. Belangeri*, Lesson. *Goonta*, Tambel, Tel.

## REPTILES OF THE

Carapax olive or brown, three keeled, edges smooth.

By no means common in the south of India, and chiefly to be found in deep tanks and large wells. [Hab. also Central India (vicinity of Chaibasa); but in Ceylon it appears to be replaced by *E. SEBÆ*, Gray. According to M.M. Dumeril and Bibron, M. Dussumier procured a young individual in a lake near Calcutta (doubtless the salt-water lake); but we have never heard of another instance, although we have seen multitudes of *Emydes* from the salt-water lake and its vicinity.—*Cur. As. Soc.*]

Length of shell of one 8 inches.

(2431) *EMIS TENTORIA*. [Col. Sykes procured another *EMYS* in the Bombay Dnkhun, *E. TENTORIA*, Gray, *P. Z. S.* 1834, p. 54, and the supposed adult *E. TECTUM* of Hardwicke's 'Illustrations.' The Society's Museum contains an adult procured by Sir A. Burnes in Sindh, and we have also a young specimen from the river Hughly. The species is most nearly affined to *E. TECTUM*, Bell, and has the same peculiar form of the fifth vertebral plate; but the fourth is quadrilateral and elongate, the third has a broad transverse posterior margin, the keels of the vertebral plates (especially that of the fourth, so developed in *E. TECTUM*), are much less prominent at all ages, the entire carapax is broader and flatter, and the abdominal plates are brown-black with pale margins, and occasionally one or two pale central spots,—instead of whitish, with two or three strongly contrasting blackish marks on each, as in *E. TECTUM*. Carapax of adult 7 in. long; that of adult *E. TECTUM* 6½ in.

I am nearly certain that the small specimen is from the vicinity of Calcutta, and that I kept it alive for some time, but did not then distinguish it from *E. TECTUM*.

(2432) Three species of restricted *EMYS* are extremely common in the neighbourhood of Calcutta, viz. *E. TECTUM*, *E. HAMILTONII*, Gray, (of which the carapax of our largest specimen measures 5½ in. in a straight line,) and *E. THURGHII*, Gray, which attains to a much larger size than the others, though adults are not often obtained. Carapax of adult from 20 to 22 in., in a straight line.—*Cur. As. Soc.*

FAM. POTAMIDÆ—or River Tortoises.

(2433) *Gen. CRYPTOPUS*—Dum. and Bibr.

Carapax with a narrow cartilaginous border—sternum wide, flexible in front and behind completely to conceal the extremities.

(2434) *CRYPTOPUS GRANOSUS*—Dum. and Bibr.

SYN. *T. granosa*, Shæpf.

*T. granulata*, Daud and Sh.

*Trionyx coromandelicus*, Mesc. Geoff., Less.

*Emyda punctata*, Bell and Gray.

*Tambel* and *Goorada gadoo*, Tel.

Shagreen freshwater Tortoise. *Eng.*

This is an extremely common species in the south of India and is found in tanks, rivers, wells, and pools of water, burying itself in the mud with great celerity. It is frequently brought to the Madras market and is eaten by many of the people there.

Length of shell of one, 3½ inches—but it becomes much larger. [Extremely common in Lower Bengal, and here also much eaten by certain classes, as indeed are all other *Testudinata*. It likewise inhabits Ceylon.—*Cur. As. Soc.*]

(2435) *Gen. GYMNOPUS*—Vide Cantor, l. c. p. 614.

(2436) *GYMNOPUS CARTILAGINEUS*—Vide Cantor, l. c. p. 615.

I have observed this species in the Godavery, the Beema and other rivers of the north west of the peninsula, but have no specimen at present.

(2437) *GYMNOPUS INDICUS*, (Gray), Vide Cant. l. c. p. 616.

I have very lately procured a specimen of this large river Tortoise taken in a net at Mahe on the Malabar Coast, where, however, it is considered rare.

Length of carapax 30 inches. [We have succeeded in obtaining only one small specimen of this in the vicinity of Calcutta.—*Cur. As. Soc.*]

FAM. THALASSIDÆ—or Sea Turtles.

(2438) *Gen. CHELONIA*—Vide Cantor, l. c. p. 617.

(2439) *CHELONIA VIRGATA*—V. Cant. l. c.

I have procured this Turtle on the East Coast of India. [Very numerous on parts of the E. coast of the Bay of Bengal.—*Cur. As. Soc.*]

(2440) *CHELONIA MACULOSA*—Cuvier.

Vertebral plates larger than broad, marked with yellow in an olive brown ground.

This Turtle is occasionally caught by the fishermen both on the East and West Coasts of India.

(2441) *CHELONIA OLIVACEA*, ESCHSCHOLTZ—Cant l. c. p. 619.

Very common in the Bay of Bengal, where I have seen many captured by ship lascars swimming out during a calm. Length of carapax average about 2 feet. [Abundant at the mouth of the Hughly.—*Cur. As. Soc.*]

(2442) *CHELONIA IMBRICATA* (L.) V. Cantor, l. c. p. 619.

I have quite recently procured this Turtle at Tellicherry on the Malabar Coast. [In the Society's Museum is a small specimen, procured in one of the Sunderbund rivers.—*Cur. As. Soc.*]

# PENINSULA OF INDIA.

## CROCODILIDÆ—Bon.

(2443) *Gen. CROCODILUS*—V. Cant. l. c. p. 621.

(2444) *CROCODILUS PALUSTRIS*, Lesson—V. Cant. l. c. p. 621.

This Crocodile, pronounced by some erpetologists only a variety of the Crocodile of the Nile, and so considered by Cantor, is very common in all the rivers and back-waters of Malabar and the West of India, very rarely seen out at sea. I have not seen it from the East Coast. It does not attain the demensions of the next species, and is considered very harmless by the natives.

(2445) *CROCODILUS POROSUS*—Schn. Cantor, l. c. p. 622.

This, the larger and fiercer of our two Crocodiles, is found in various localities both on the East and West Coasts, and is the species so abundant in the fort ditch at Vellore. It is of very rapid growth. An egg brought from Vellore to Walter Elliot, Esq., was hatched in the Government house compound, and in eight years had increased to the length of 8 or 9 feet, becoming so powerful as to destroy a full grown buck Antelope which had come to drink water at the tank where it usually resorted.

Both of these species of Crocodile are called Alligators by the English in India; erroneously so of course, as no Alligators have as yet been found in the old world.

## FAM. CHAMÆLEONIDÆ.

(2446) *Gen. CHAMÆLEO*, Laurenti.

Feet thin with 5 fingers joined to the nails into two lobes, one of two, the other of three fingers. Skin granular. Eyes large, covered by the scales of the eyelid except one small round aperture. No visible tympanum.

(2447) *CHAMÆLEO ZEYLONICUS*—Laur.

Dorsal crest short; abdominal crest with the spines long and somewhat distant. Colour green.

Syn. *C. vulgaris*, var. B, Dum. and Bibr. *C. zebra*, Bory de St. Vinc. *C. calcaratus*, Merr.

I have no hesitation in considering this Chameleon distinct from the African one, as well on account of the slight but permanent structural distinctions (the abdominal ridge being in the African one composed of very short and closely set spines), as the difference of locality, and the great difference in the change of colour of the two. In our Indian one, the only change produced is from one shade of green to another. In a state of quiescence it is usually very pale green, sometimes dark blackish green; but when excited it is mottled or *zebra'ed* very prettily with dark transverse blotches on a pale ground. I never saw any pure yellow, or red in any state. A very fine one which we long kept, as-

sumed a tolerably pure yellow ground tint occasionally, with black markings.—*Cur. As. Soc.*

It is found in all the wooded districts of India. It is used in medicine by some of the native doctors, and may generally be procured in the Madras market.

Length of one 10 inches, of which the tail is more than half.

(2448) *CHAMÆLEO PUMILUS*—Latreille.

Head tuberculated; dorsal crest continued over the tail. Some large circular scales mingled with the small and unequal granulose ones.

I possess a specimen of this small Chameleon in spirit, which was said to have been taken near Coonoor on the Nilgherries.

Length  $5\frac{1}{2}$  inches, of which the tail is nearly 2.

## FAM. GECKONIDÆ, Bonaparte.

(2449) *Gen. HEMIDACTYLUS*, Cuvier, Cantor, l. c. p. 628.

(2450) *HEMIDACTYLUS TRIEDRUS*—Daud.

Syn. *Deowur bullee*, Tel., of the Yanadees.

Many large triedral tubercles mixed with the other scales—tail somewhat rounded—several large transverse brown bands marked with large white triedral scales—7 or 8 femoral pores in each thigh in the males.

This very handsomely marked Gecko is rarely found in houses, being chiefly met with in jungly places, on rocks and trees, in all parts of the country, but is nowhere common.

Length of one 7 inches, of which the tail is about half.

(2451) *HEMIDACTYLUS SUBTRIEDRUS*—n. sp.?

*H. TRIEDRUS*—var.?

*Sookka bullee* of the Yanadees.

Differs from *TRIEDRUS* in somewhat shorter head, in the scales of the throat and muzzle being smaller in its shorter head; fewer dark bars on the back and fewer of the white tubercles; and in the triedral scales generally being smaller. It is equal in size to *TRIEDRUS*, and the number of femoral pores is the same. Colours much as in *TRIEDRUS* but paler.

Length of one  $6\frac{1}{2}$  in., of which the tail is more than half.

The Yanadees, a peculiar jungle race in the Nellore district, who have a considerable knowledge of reptiles; pronounced this to be a distinct species from the last, and gave it a peculiar name or I should have put it down as a casual variety of *TRIEDRUS* without closer inspection. It is found chiefly in rocks, seldom entering houses. It forms a link between *TRIEDRUS* and *MACULATUS*.

(2452) *HEMIDACTYLUS MACULATUS*—Dum. and Bibr. Qu. II. *FÆNATUS*, D. and B. ? *Our. As. Soc.*

Brown or olive-green with dark marks; back furnished with numerous sub-triedral tubercles.

## REPTILES OF THE

This is the most common species of Gecko in the South of India, but never attains here the dimensions stated by Dumeril and Bibron. It is very subject to variation both in the ground tint and the dark markings, which it appears to have the power of deepening or reducing.

Length of an average specimen  $4\frac{1}{2}$  inches, of which the tail is  $2\frac{4}{10}$ ths.

(2453) *HEMIDACTYLUS PUNCTATUS*—n. sp.

Back with some larger conical scales, and sub-caudal scutæ very large; scales of abdomen dotted, brown above; limbs and tail reddish with dark bands: a pale yellow streak from muzzle to tail bordered beneath by a dark line; another dark line from nostrils to behind the eye—beneath yellowish white—some of the sub-caudal scutæ orange.

Length  $3\frac{3}{8}$  inches, of which the tail is  $1\frac{1}{2}$ .

I procured a single specimen of this small Gecko lately, in a house at Tellicherry. At first glance, I took it for *maculatus*. It appears very similar to *H. frenatus*, but I can find no pores, and the thumb appears as well developed as in *maculatus*.

(2454) *HEMIDACTYLUS LESCHENAULTII*—Dum. and Bibr.

Small tubercles scattered sparingly among the very small scales of the back, 13 femoral pores in each thigh. Adult pale gray above; young with dark markings and tail annulated black and white.

Length of one nearly 6 inches, of which the tail is  $2\frac{5}{10}$ ths.

This species of Gecko is very common throughout the South of India in houses. I have not observed the mode of coloration described by Dumeril and Bibron.

(2455) *Gen. HOMONOTA*. Gray.

(2456) *HOMONOTA FASCIATA*. Jerdon.

Body covered above with large imbricated, keeled and pointed scales, below with much smaller hexagonal scales, ranged in oblique series: the throat and limbs studded with minute hexagonal scales, larger on the thighs; and the head uniformly covered with hexagonal plates, smaller than the scales of the back. A range of simple labial plates above and below, the rostral larger, bordered on the lower jaw with a series of small oval plates, and these with a second series of smaller oval plates. Tail wanting in the specimen. The pupils appear to be round. Colour plumbeous brown, with 7 or 8 irregular broad whitish cross-bands, formed each of three or more contiguous spots. An omega-like mark on the forehead. Length of head and body  $1\frac{1}{2}$  in. of head  $\frac{3}{8}$  in. This specimen was sent many years ago to the Society's museum by Mr. Jerdon.—*Cur. As. Soc.*

(2457) *Genus GYMNOACTYLUS*. Wiegman

—Vide Cantor l. c. p. 861

(2458) *GYMNODACTYLUS INDICUS*—(Gray.)

SYN.—*Goniodactylus indicus*, Gray.

Scales of body and tail small, equal; those beneath the tail larger.

This species, lately [Ann. and Mag. of Nat., Hist., Dec. 1846, p. 429.] described from specimens sent home by myself, is found on the Nellocherries, concealing itself under stones in the day time. I have procured it on the top of Dodabetta, the highest mountain of the group, and have also found it in Coorg. Its colours when fresh are a mottled brown, or greenish-brown, with a row of orange-yellowish spots along the back edged darker, and a line of similarly coloured spots on each side; lips also of the same tint, and the lower portion of the tail.

Length of one  $2\frac{4}{10}$  inches, of which the tail is  $1\frac{2}{10}$ th.

(2459) *GYMNODACTYLUS MALABARICUS*—n. sp.

Scales of the back uniform, small, granulose, a few at the root of the tail between the two hind legs smaller, those in the tail above larger, imbricated; a few small spines at the root of the tail: dark brown above, marbled with black spots and a white spot on the nape.

Length of one  $2\frac{4}{10}$  inches, of which the tail is about half.

I have only very recently procured this small Gecko from the forest of Malabar, where it frequents large trees and rocks. It is generally to be found on those large trees, whose base is protected by buttresses, in the inequalities of which it finds a secure retreat, and occasionally it hides itself under a cleft in the bark. The dark markings on its back are edged lighter, and it is of a bluish white colour beneath. It is of a more slender habit than the preceding species.

(2460) *GYMNODACTYLUS LITTORALIS*—n. sp.

Very slender form, scales of back small, equal those on the muzzle larger; beneath the tail a series of large six-sided scales. Colour pale brown, with a series of paler marks along the and tail, a black spot on the nape, the chin and throat pale yellow.

Length  $2\frac{3}{10}$  inches, of which the tail is  $1\frac{1}{10}$ th.

I procured a single specimen of this well marked species of Gecko in a ware-house on the Sea Coast in Malabar, and have not yet been fortunate enough to find another.

(2461) *GYMNODACTYLUS MYSORIENSIS*—n. s.

Scales of the back uniform, granulose, with 2 or 3 rows of spines on each side, and on the tail; tail beneath with a triple series of large uniform scutæ.

Head and back covered with small granulose scales, and two or three distant rows of spines on each side and extending along the tail; chin and throat covered with small hexagonal scales, gradually changing to rounded imbricated scales.

## PENINSULA OF INDIA.

which cover the abdomen ; scales of tail imbricated, with 8 rows of larger nail-shaped scutæ beneath ; scales of the basal joints of the fingers and toes, enlarged, nail-shaped.

Body above greenish-brown, with a light stripe down the centre of the back, and a series of dark brown marks on the head, back and sides ; legs and feet banded ; beneath bluish-white ; chin, throat and anterior portion of palpebræ bright yellow.

Length  $2\frac{1}{2}$  inches, of which the tail is  $1\frac{1}{4}$ .

I have quite recently found this small and very distinctly characterized species of Gecko at Bangalore, frequenting rocks and also entering out-houses. The young has the tail flesh-coloured : 2 femoral pores on one side and 3 on the other.

### FAM. IGUANIDÆ.

(2462) *Gen.* CALOTES, Cuv.—Vide Cant, l. c. p. 636.

(2463) CALOTES VERSICOLOR, (Daud.)

Syn. *Agama Tiedmanni*, Kuhl.—*A. vulturosa*, Harl.

Two spines on each side of the nape. No fold on the neck. Tail conical. Scales large, keeled.

This is the most common and extensively distributed lizard in the country, being found everywhere in gardens, avenues and jungles. Though not a Chameleon in structure, it is yet one in habit, and much more so than our Chameleon. Its usual tints are a pale drab or fawn colour, but this it changes to bright red, to black and to a mixture of yellow red and black. This change is sometimes confined to the head, at other times diffused over the whole body and tail. A common state to see it in, is seated on a hedge or bush with the tail and limbs black, head and neck yellow picked out with red, and the rest of the body red. I am inclined to think that this display of colours is merely seasonal. It only occurs in the males, the females being uniformly and plainly coloured. The young has a pale band on each side of the body from the eye to the tail, and a series of dark bands on the back. Mr. Blyth mentions, in a notice of this lizard in the Journ. As Soc. for 1842, p. 870, that its usual colour is \* \* \* \*. This is somewhat remarkable and I should doubt if it was the same species. Are the changes mentioned here observed in Calcutta ? [I never saw any yellow in a Bengal specimen ; and some which Dr. Kelaart sent me alive from Ceylon were perfectly identical with the Bengal reptile. It is chiefly during the months of May and June that the species here displays its fine colours ; which generally are—head and neck, and more or less of the fore-part of the body, bright red ; rest of body and limbs dark greenish-brown ; and a great black patch on the shoulder. The female is small-

er, and deposits her 8 to 16 eggs very commonly in a flower-pot, burrowing 4 or 5 in. into the hard dry soil, and finally covering them up most carefully, so that no appearance remains of the ground having been disturbed. The young appear in about 8 or 9 weeks. I have seen a two-thirds grown lizard of this species carry off and partly swallow a Scolopendra nearly of its own length.—*Cur. As. Soc.*]

This and the other species of Calotes are essentially tree lizards, seeking their prey often on the ground, but always retreating up trees when in danger.

Length of one specimen 18 inches, of which the tail is 12.

(2464) CALOTES NEMORICOLA, nov. spec.

One detached spine in front of 2 or 3 small ones on each side of the nape. A fold of skin on the shoulder, scales of the sides very large, not keeled, those of the abdomen much smaller, keeled. Dorsal crest extending only about one-third along the back ; colour green.

I only procured one specimen of this lizard near the foot of the Coonoor ghat of the Nilgherries. Compared with *versicolor*, the large smooth scales are the most prominent feature of distinction. The scales at the base of the tail above are of rather large size, keeled and pointed. The tympanum is large : where the dorsal crest terminates, the scales of the ridges are pointed.

Length of my specimen 18 inches, of which the tail is 8.

(2465) CALOTES ROUXI.—Dum. and Bibr.

An oblique fold in front of each shoulder. Scales of the sides small, nearly as large as those of the abdomen. Base of the tail above furnished with much larger scales, somewhat angular. Colour pale brown with darker bands.

I have lately procured from the forests of Malabar a species of lizard, which appears to correspond with the description of *C. Rouxi* from the Burmese country. I found it more abundant than elsewhere in a small wooded island known as Pigeon I., about 20 miles S. S. W. from Honore. The usual change of colour consists in the head and nape becoming brick red, and the rest of the body blackish.

Length of one 11 inches, of which the tail is  $7\frac{1}{4}$ . [This coloration is altogether dissimilar from that described of my supposed *C. Rouxi* from Newera Elia, vide *J. A. S.* XXI, 354.—*Cur. As. Soc.*]

(2466) CALOTES VIRIDIS, Gray.

Nape with 2 isolated spines above the ears ; a high crest on nape and shoulders diminishing along the back and lost on the root of the tail, scales large above, smaller beneath, those at base of the tail largest. I always considered that the very pretty green lizard which I had procured

## REPTILES OF THE

from Travancore and the southernmost portion of Malabar agreed tolerably exactly with the description of *C. ophiomachus*, but Mr. Gray has described it as new by the name of *viridis*. Ann. Mag. Nat. Hist. XVIII, page 429. [There appears to be some confusion here. The present species we consider to be, decidedly, *C. OPHIOMACHUS*, as figured by Daudin; and its range extends to Ceylon and to the Nicobar islands. The *C. VIRIDIS*, Gray, was long ago presented by Mr. Jerdon to the Society, and it does not correspond with Mr. Jerdon's present descriptions, either of this or of the next species; yet his figure sent of the supposed *OPHIOMACHUS* would seem to present *C. VIRIDIS*.—*Cur. As. Soc.*]

The colour is a bluish-green with 4 or 5 transverse stripes of reddish white, and some of the scales of the throat are edged with orange.

Length  $16\frac{1}{2}$  inches, of which the tail is nearly 13.

### (2467) *CALOTES OPHIOMACHUS*.

A small crest of long spines on each side of the nape. Dorsal crest extending to the root of the tail, which is long, conical, and very thin towards the end. Green; with transverse bands.

Mr. W. Elliot possesses a rough drawing and brief description of a green lizard, distinct from any of those previously described, which I believe to be identical with the *C. ophiomachus* of authors. He procured the specimen in Dharwar. Its dimensions were as follow:

Length 14 inches, of which the tail is 10.

The drawing represents the colours to be pale green with dark transverse bands, interrupted by a pale longitudinal line from ear to tail.

### (2468) *Gen. SALEA*, Gray.

Differs from *Calotes* in the series of scales pointing directly backwards, or running in longitudinal lines; not as in *Calotes*, where the points are directed upwards, nor as in *Bronchocele*, where they are directed downwards.

### (2469) *SALEA JERDONI*, Gray.

Nuchal and dorsal crest formed of elongated compressed scales; tail with a keeled crest.

This pretty lizard, described by Mr. Gray from specimens sent home by me, is found in the Nilgherries where it frequents bushes, hedges and gardens. [Hab. also Ceylon (Newera Elia), whence a specimen was presented by Dr. Kelaart to the Society's Museum, since purloined together with a *SALEA* from the Nicobars.] Its colour is a bright grass green marbled with brown, some red marks on the head and nape and a few white scales on the sides. It does not appear to possess the faculty of changing its colours.

Length of one  $9\frac{1}{2}$  inches, of which the tail is  $6\frac{1}{2}$ .

Another, from Mirzapore (?), presented by the late Major Wroughton, may be described as,

(2470) *SALEA GULARIS*, Blyth. Length  $16\frac{1}{2}$  in., of which the tail measures  $11\frac{1}{4}$  in. Structure typical. Hind-limb reaching to the articulation of the lower jaw. Series of 14 lengthened spines from occiput to behind the shoulders, increasing in length to the 7th and 8th, and then successively diminishing. Gular faun, or dewlap, well developed. Two inconspicuous ridges of slightly lengthened spines above the tympanum.—*Cur. As. Soc.*]

### (2471) *Gen. SITANA*, Cuv.

Four toes on the hind-feet, no dorsal crest, a large dewlap in the males.

### (2472) *SITANA PONTICERIANA*, Cuv.

Fawn-coloured, rhomboidal dark spots on the back, and a pale longitudinal streak from ear to tail. Male, in breeding season, with a large tricoloured dewlap.

This common ground lizard is distributed over all India, I believe, but is rare in the wooded districts, frequenting the open country, field and low copses: on the approach of danger, it runs with great rapidity, tail erect, and conceals itself in any crack in the ground or hole, or under a stone or bush. Notwithstanding its activity, it is the common prey of harriers, buzzards, hawks and eagles. I have not seen the beautiful dewlap (blue, black, and red) developed in the south of India, nearly to the extent that appears to take place in the north, and there it attains a greater size. The colours of the dewlap are only exhibited during the pairing season, and it then becomes larger than previously. At this time, too, some blue marks are observable on the nape and back, that on the nape indeed forming a kind of crest more conspicuous now, the colours in general too are deepened, and the quadrangular marks on the back and barring of the limbs very distinct. The name *Sitana*, said by Cuvier to be the name by which it is known at Pondicherry, is a Latin termination of the word *Shaitan* or Devil, a name sometimes applied to it by the Musulmans of S. India.

Length of one  $6\frac{3}{4}$  in., of which the tail is  $4\frac{5}{8}$  in.

### (2473) *Gen. DRACO*, Linne—Vide Capt. l. c, p.

### (2474) *DRACO DUSSUMIERII*—Dum. and Bibr.

Anterior and posterior angles of each orbit edged by a small pointed horn; grey, wings marked black and red.

This very beautiful little lizard is only found in the forests of the West Coast, or rather in the neighbourhood of the forests, for it frequents cocoa-nut and betel-nut plantations: in their vicinity chiefly, not living, it is alleged, in the woods themselves, nor in the gardens at any distance from the forest. It is tolerably common in all Malabar, Cochin and Travancore, but not known farther North than Malabar, being either unknown or very rare in Canara.

The colour of the body is a delicate grey with some darker markings, which the animal occasionally renders very distinct, at other times obscures entirely. It sometime also changes its whole hue to a dark blackish grey. The ground colour of the wings is red marbled with black and edged with yellow. The small dewlap is pale yellow marbled with green at the base. This I may remark is never extended forwards to the extent usually seen in stuffed specimens, being merely brought forward now and then to the edge of the chin, and in a flat state not distended with air. The two lateral appendages of the head, also, are merely slightly raised now and then, and never distended in the manner seen in dried specimens.

(2475) *Gen. AGAMA*, Daudin.

Head short, triangular; nostrils near the muzzle: 2—5 incisive teeth in upper jaw; a longitudinal fold beneath the throat and another across the neck. Tail compressed, conic. Anal pores.

(2476) *AGAMA DORSALIS*—Gray.

Nostrils small, somewhat tubular; occipital plate very small, simple; a small group of spines behind the ear, which is large. Dorsal crest almost wanting; scales above small, equal, keeled, those beneath smooth.

This large rock lizard is only partially distributed in Southern India, and is only found at some elevation above the sea. It is most abundant in Mysore, and especially so in the neighbourhood of Bangalore, where it may be seen on every bare rock about. It is also not uncommon on the edges of the Nilgherries up to the height of nearly 6000 feet. Its normal colour and that of the female at all times is a dusky grey with dark markings. The male can assume a very bright livery, viz. fine vermilion red above, with a streak through the eye; under surface, limbs and tail black: occasionally the red is exchanged for yellow. It frequents bare rocks only, and retreats into holes and clefts on the approach of danger.

Length of a fine male 16 inches, of which the tail is  $10\frac{1}{2}$ . [The Society possesses a specimen from Pind Dadun Khan, presented by W. Theobald, Esq. Jur.—*Cur. As. Soc.*]

#### FAM VARANIDÆ.

(2477) *Gen. VARANUS*—Vide Cantor l. c. p. 633.

(2478) *VARANUS DRACÆNA* L. (*Query Linne.*)  
*Tupin. Bangalensis*; Daud.

*V. guttatus*) Merr.

*V. argus*, Merr.

*Tup. cepedianus*, Daud. and Kuhl.

*V. punctatus*, Merr. and Less.

*Mon. gemmatus*, Guer. Ic. R. A.

*V. Bibroni*, Blyth. *J. A. S.* 1842, p. 866.

Nostril situate exactly between the eye and

muzzle. Tail compressed with a strongly dentated ridge.

This species of Monitor appears generally spread throughout the whole of India. It is chiefly nocturnal in its habits and frequents jungly places. It is by no means confined to the neighbourhood of water, though perhaps it prefers such a locality. It defends itself most vigorously by striking with its tail. It can climb well both trees and walls, and it is popularly believed, that thieves make use of it to effect an entrance into a building or over a wall by allowing the guana to get hold by its fore-claws of the window sill or wall and pulling themselves up by it. It is eaten by the natives, who consider it highly nourishing and aphrodisiac, and many Europeans use it for soup, imagining it allied to the West Indian Guana. It can always be procured in the Madras market.

Length of one 44 inches, of which the tail is 25. [The largest specimen in the Society's Museum measures 52 in.; and our largest of *Hydrosaurus salvator*, (Laur.). 78 in., or exactly the same as that of *H. giganteus*, Gray, in the British Museum. *Empagusia flavescens*, Gray, our third common Monitor of Lower Bengal, we have not known to exceed 3 ft. in length. The Society has lately received a large specimen of *Hydrosaurus salvator* from Ceylon; and *Empagusia flavescens* likewise inhabits the Indus territories.—*Cur. As. Soc.*]

#### FAM. LACERTIDÆ.

(2479) *Gen. CALOSAURA*—Dum. and Bibr.

Maxillary teeth simple and tricuspid. Nostril placed on the *canthus rostralis*. A small fold of skin in front of the shoulder; abdominal scutæ quadrilateral, smooth placed in longitudinal bands; 5 fingers and 5 toes; tail square at the root, round for the rest of its extent.

(2480) *CALOSAURA LESCHENAULTII*, Dum. and Bibr.

Dorsal scales rhomboidal, keeled; six rows of longitudinal scales on the abdomen.

Reddish brown above, pale yellow beneath, sides dark brown with 2 pale yellow bands, tail red.

Length of one  $5\frac{2}{10}$ th in., of which the tail is  $3\frac{1}{2}$ .

This pretty little ground lizard is somewhat locally distributed. I have seen it in the Salem and Coimbatore districts only, especially near the banks of the Cavery. It frequents bushy ground hedges of Euphorbia and clumps of Cactus, under which it rapidly takes shelter, as also among rocks. [The Society's Museum contains examples of what we take to be this species from Pind Dadun Khan, in the Punjab Salt Range; and formerly possessed the same from Afghanistan.—*Cur. As. Soc.*]

(2481) *Gen. ACANTHODACTYLUS*, Fitz.

# REPTILES OF THE

One naso-rostral plate, ventral lamellæ quadrilateral, smooth. Fingers and toes compressed, toothed.

(2482) *ACANTHODACTYLUS NILGHERRENSIS*—n. s.

Anterior edge of ear toothed scaly, collar transverse, scales of back somewhat larger behind than in front, an occipital plate.

This lizard, apparently belonging to a genus new to India, was obtained by W. Elliot, Esq. on the Nilgherries near Coonoor. I have not myself been fortunate enough to observe it, and know nothing of its haunts. Its colours in spirit are of a pale pearl grey with a row of black spots on its back, another row on its sides somewhat larger and white edged black.

Length of one  $5\frac{1}{2}$  inches, of which the tail is 3. [A specimen with tail imperfect was long ago presented by Mr. Jerdon to the Society's Museum—*Cur. As. Soc.*]

## FAM. SCINCIDÆ.

(2483) *Gen. MOCOA*, Gray.

●(2484) *MOCOA BILINEATA*, Gray, Ann. Nat. Hist. Dec. 1846, p. 430.

Fronti-parietal plates two separate; ears round, moderate, with two very indistinct minute scales in front; the drum sunken; scales 6 or 8 rowed, thin, smooth: above shining olive, whitish beneath, a dark broad line on each side from nostril to end of tail. In the young and half grown animal, the tail is of a beautiful smalt or violent colour.

Length of one  $5\frac{1}{2}$  inches, of which the tail is  $3\frac{1}{2}$ . [Remarkable for its *Riopa*-like proportions, and great length of tail; also for having four large acutely triangular præ-anal scales, with the points converging posteriorly.—*Cur. As. Soc.*]

I have only found this Scink under stones on the summit of the Nilgherries. It appears very similar to *Lygosoma Dussumerii* of Dumeril and Bibron.

(2485) *Gen. RIOPA*, Gray.

(2486) *RIOPA ALBOPUNCTATA*, Gray, l. c.

Pale olive brown, yellowish white beneath, sides of one 4 inches, of which the tail is not quite 2.

This certainly looks very like the *Tiliqua pulchra* figured in Gray and Hardwicke's Illust. of Indian Zoology. I have found it in the Nellore district, where it is rare. [The Society has lately received it from Mergui.—*Cur. As. Soc.*]

(2487) *RIOPA PUNCTATA* (L.) Gray.

Length of one 9 inches, of which the tail is  $4\frac{3}{4}$ .

I have found this lizard both on the Eastern and Western Coasts of India under stones, or in the ground.

(2488) *RIOPA HARDWICKII*, Gray.

Very similar to the last, but with a longer and more pointed muzzle, and brighter colours, the stripes on the back being generally more distinct, and the tail, in the young, bright vermilion red. I have only found it in the Carnatic, where it is not very rare.

Length of one 9 inches, of which the tail is 5. It is found concealed in dark places, under logs of wood, stones, &c. [Hab. also Ceylon.—*Cur. As. Soc.*]

(2489) *Gen. TILQUA*.

(2490) *TILQUA RUFESCENS*, Merr.

*T. carinata*, Gray.

*Euprepes Sebae*, C. and B.

This is the most common Scink in the country, being universally dispersed throughout India, hiding itself under leaves, rubbish, stones, in dark rooms, &c. It runs with some rapidity, and is very active. Those I have seen in the Carnatic have the two yellow bands on the sides well developed, and appear to belong to the varieties A. and B. of Dumeril and Bibron, whilst on the Malabar Coast the variety D. and E. only is to be seen. [Those of Bengal are constantly banded, so far as we have seen; and the sanguine red colour of the lower band seems to denote the breeding season. In a very large specimen taken lately in my own garden (length 12 in., of which the tail measures  $7\frac{1}{2}$  in.), the bands are nearly obsolete.—*Cur. As. Soc.*]

Length of one 9 inches, of which the tail is  $5\frac{1}{2}$ .

(2491) *TILQUA TRIVITTATA*, Gray.—Gray and Hardwicke's Ill. Ind. Zool.

Very similar to the last, but with the head shorter and more triangular, scales of the back broader, and three stripes along the back.

Length of one 8 inches. of which the tail is  $4\frac{3}{4}$ .

Mr. Gray, in his description of the *Euprepes trilineata*, mentions that his *Trivittata* is yet unknown in Europe. I possess two specimens, which correspond exactly with the figure in Hardwicke's 'Illustrations.' I procured my specimens at Jalnah, where it is the common species.

(2492) *TILQUA RUBRIVENTRIS*, Gray.—Gray and Hardw. Ill. Ind. Zool.

Olive brown above, beneath yellowish, usually red on the throat only, at times the whole abdomen red, sides white-spotted on a dark ground, row of black spots on centre of back, and some other smaller ones on each side; three keeled scales.

Length of one  $6\frac{3}{4}$  inches, of which the tail is  $3\frac{5}{10}$ ths.

This pretty Scink is tolerably common in wooded places, lurking about chiefly among fallen leaves. It is more abundant on the West Coast

## PENINSULA OF INDIA.

than in the Carnatic. The red colour of the abdomen is, I think, seasonal, and confined to the males. Mr. Gray mentions that, before my specimens were sent home, it was only known by the figure in Hardwick. [The Society has a small specimen from Assam which may be *T. MULTICARINATA*, (Kuhl?), apud Gray. Scales distinctly seven-keeled. Colour greyish olive-green above, with dark spots on the hinder part of the body and base of tail. Lateral band, commencing from the ears, dark olive, with three narrow whitish stripes along the basal half of the tail, which are broken into spots on the sides of the body. Terminal half of tail whitish. Below also white, with obscure dark striæ.

(2493) *Gen. EUPREPES*.

(2494) *EUPREPES TRILINEATA*—Gray, l. c.

Ears with two elongated scales in front, scales five-keeled, above pale yellow brown, beneath yellowish white, 3 white stripes edged with black on anterior half of the back, legs reddish.

Length of one  $7\frac{2}{10}$  inches, of which the tail is nearly 4.

This well marked species is locally distributed. I have found it only in sandy ground, near the sea in the Carnatic, concealing itself in holes and fissures, and under shrubs.

I procured, on one occasion, a specimen of a small Scink in the forests of Malabar, which appeared distinct from any of the previous ones. It was uniform dark above and whitish beneath, body compressed, and scales two-keeled. Unfortunately, however, it was destroyed before I made a full description of it. I may here mention that *Goniodyctylus indicus*, *Calotes viridis*, *Salea Jerdoni*, *Mocia bilineata*, *Riopa albopunctata*, and *Euprepes trilineata*, were described by Mr. Gray from specimens sent home by me to the British Museum.

*Reptiles of the Peninsula of India* By T. C. JERDON, Esq., Madras Medical Service. Beng. As. Soc. Journ. No. 6 of 1853, p. 522 to p. 534.

The following is merely a brief and imperfect resume of the serpents and frogs of S. India, drawn up from my drawings, with a few rough notes attached to them; as circumstances have prevented my giving a more full account at this time; but a detailed account will be drawn up, as soon as I have again access to my collection.

### OPHIDIA.

#### VENOMOUS SERPENTS.

##### FAM. VIPERIDÆ.

##### SUB-FAM. BUNGARINÆ.

##### TERRESTRIAL.

(2495) *ELAPS MELANURUS*, (Shaw)—Russell l, pl. 8.

I never procured but one specimen of this lit-

tle snake. It was at Jalnah and about 14 inches long. It was red beneath the tail and was very bold. Scutæ 234. Scutellæ 28. 13 rows of scales. Common in Burmah.—*Cur. As. Soc.*

(2496) *ELAPS MALABARICUS*—n. s.

Head black with transverse bands, body brown above with black markings, bright red beneath. Scutæ 246. Scutellæ 38. 13 rows of scales. Tail exceeds  $\frac{1}{10}$ th of total length.

I have found this little snake in forest in Malabar, once or twice during the monsoon. The red colour of the abdomen fades in spirits.

(2497) *BUNGARUS CANDIDUS*—L., Russell l, pl. 1.

*B. semi-fasciatus*, Schl.

"Yenna vyrien" of the Tamools.

Up to 3 feet in length. Is very common all over Southern India, and is said to be fatal. Scutæ 217. Scutellæ 39.

This snake may be distinguished from one or two harmless species that much resemble it in colour, by the subcaudal scutellæ being in one row, not double.

(2498) *BUNGARUS FASCIATUS*—Russell l, pl. 3. Golden banded bungarum.

I have only seen specimens of this handsome snake in the Northern Circars at Ganjam, where it is not very common. It is said to be very deadly.

##### SUB-FAM. NAJINÆ—Bon.

(2499) *HAMADRYAS OPHIOPHAGUS*—Cantor?

*Naia vittata*—Elliot?

*Sankarachur* and *Shakha-muti*, Beng.

I once had a magnificent snake of this genus sent me which had been killed in forest in the Wynaad. It was  $12\frac{1}{2}$  feet long. Scutæ 225, Sub-caudal do. 12. Scutellæ 64.

I am inclined to think that it may be a different species from the Bengal serpent, for it was of an uniform dark olive colour above, without any appearance of bands. The specimen was unfortunately destroyed. One, 9 ft. long, which I procured about 20 miles S. of Calcutta, and now in the Society's Museum, is banded throughout.—*Cur. As. Soc.*

(2500) *NAIA LUTESCENS*—Russ. l, pl. 6. Cobra.

Naga pambu, or Nella pambu—Tam.

But too common all over India.

##### SUB-FAM. VIPERINÆ—Bon.

(2501) *TRIGONOCEPHALUS NEPA*—Laur.

*Cophias hypnale*—Merrem.

Scutæ 142. Scutellæ 39. 17 rows of scales not uncommon in forests in Malabar. I have not seen it longer than 16 or 17 inches.

(2502) *TRIGONOCEPHALUS ELLIOTI*—n. s.

Form massive; 23 rows of scales on the body; Scutæ 151, Scutellæ 43. Olive-green above;

## REPTILES OF THE

—pearl-white beneath; poison-fangs small; head covered with plates. Up to 2 feet and upwards long.

I have only procured this on the Neelgherries towards the lower portion of the plateau. Dr. Cantor tells me that "the shields of the crown of the head resemble those of *Trig. blanchoffi*, Schlegel."

(2503) *TRIGONOCEPHALUS (COPHIAS) VIRIDIS*—Merrem. Russ. 1, pl. 9.

21 rows of scales, 154 Scutæ, 60 Scutellæ. Rare, I have only got it from the Eastern Ghats.

(2504) *TRIGONOCEPHALUS (COPHIAS) MALABARICUS*—n. s.?

Very closely allied to *T. nigromarginatus*. Has 21 rows of smooth scales. Scutæ 145 to 149. Scutellæ 48 to 53. Green above, with brown transverse and zigzag markings. Up to 2 feet long nearly. Not uncommon in all the forests of the West Coast.

(2505) *TRIGONOCEPHALUS (COPHIAS) NEELGHERRIENSIS*—n. s.

• Of small size, dark brown with black markings. 23 rows of carinated scales. Scutæ 142. Scutellæ 36. Not uncommon in woods on the Neelgherries.

(2506) *TRIGONOCEPHALUS (COPHIAS) WARDII*—n. s.?

Has 21 rows of carinated scales. Scutæ 154. Scutellæ 51. Greenish colour, with purplish-brown diamond spots on back and sides; 12 to 14 inches long. The scales of the head resemble those of *T. sumatranus*, Raffles, according to Cantor (*in literis*).

(2507) *VIPERA RUSSELLII*—Gray. Russell 1, pl. 7.

"Kunnadi vyrien" of Tamools.

This well known and justly dreaded snake grows to a large size. I am strongly inclined to believe that the far famed *Cobra monil*, or *Cobra manilla* of some, is merely the young of this species. The old orthography is *monil*, which simply means a chain or necklace, and whoever looks at the markings of this snake, especially of the young one, must be struck with the resemblance thereof to a necklace. I need hardly remind the reader that both *Cobra capella* and *Cobra monil* are Portuguese names, and I have little doubt, that the latter name was given to our present species by the Portuguese. It has however been forgotten as applied to this viper, and may now be considered a fable; for every one you meet is able, on his own showing, to point you out the *real Cobra monil* as quite distinct, and what is more remarkable, no two observers describe it alike, they only agree in its being a very deadly snake. I may here add that the *carpet snake*, another household word in the Madras army, appears to me to be equally fabulous, as I have not been able to identify it among the

venomous snakes, several prettily marked innocent species having been, at different times pointed out to me as the carpet snake. Generally, I think, the little harmless *LYCODON AULICUS* (as indeed mentioned afterwards by Mr. Jerdon); and this, perhaps, from its habit of entering houses as much as from its markings.—*Cur. As. Soc.*

(2508) *VIPERA ECHIS*—Schlegel. *V. noratta*—Shaw. Russell 1, pl. 2.

"Kutta vyrien" of the Tamools.

This little snake is very common in the Carnatic. I do not think its bite would prove fatal to man. I have known a dog bitten by one to recover.

The above are all the venomous land snakes I have yet met with in Southern India. Of these the only ones at all common are the Cobra, the Chain Viper (*Vipera Russellii*), the *Bungarus candidus*, and the little *Vipera echis*. Most of the others are peculiar to the forests of India. The *Trigonocephali* are not usually fatal. I have known several cases of bites by *Trigonocephalus malabaricus*, and *Trig. nepa*; and none proved fatal. Great pain is experienced, and swelling usually follows, but the patient gradually recovers. I myself was bitten in the fore finger by the *Trigonocephalus neelgherriensis*; I applied a ligature round the finger, and sucked the wound vigorously. In a minute or so the skin round the bite blackened, and in a minute or two more a perfectly circular bit of the skin came off in my mouth. I set off running immediately I was bitten, and felt no further ill effects. See Cantor's remarks on the bite of *Trig. Sumatranus*, Journ. As. Soc., Calcutta, XVI, 1044-6; also Blyth, *ibid.* XX, 524.

### PELAGIC.

#### FAM. HYDRIDÆ.—Bon.

(2509) *HYDROPHIS COLUBRINA*—Schlegel var. ?—In. s.

I possess what is apparently a variety of this species of sea-snake. It differs from the finished drawing of the species in Cuvier's *Regne Animal* (Edit. des Eleves), in the black markings meeting on the back and abdomen, thus forming a series of light-colored oval spots on the sides; the abdominal scutæ commence nearer the mouth, having only 3 or 4 series of small scales between them and the elongated mentals; the scutæ are above 300 in number, and the rows of scales are from 35 to 45—whilst in *H. colubrina* the scutæ are only 246—and the rows of scales 25. My only specimen is a young one procured at Madras.

(2510) *HYDRUS SCHISTOSUS*, Daud.—Russell 2, pl. 10.

Up to 4 feet long nearly. Very common at Madras.

## PENINSULA OF INDIA.

(2511) *HYDRUS PELAMIDOIDES*, Schlegel.  
Not common at Madras.

• (2512) *HYDRUS BICOLOR*, Schneider—Russell 1, pl. 41. Rare at Madras.

(2513) *HYDRUS STRIATUS* Lacép.—Russell 2, pl. 9? Not rare at Madras, up to 6 feet in length.

(2514) *HYDRUS NIGROCINCTUS*, Daudin.—Russell 2, pl. 6. Common at Madras.

(2515) *HYDRUS CANTORI*, n. s.—II. *NIGROCINCTUS*, var.—Cantor, J. A. S. C. XVI, 1050.

Dr. Cantor described this as a variety of the last, in his valuable Catalogue of Malay Reptiles.

I forwarded him a specimen in 1848, and he remarked as follows on it. "From the examination of this specimen, the second I have seen, I am induced to believe it a distinct species, and not a variety of *nigrocinctus*." It differs from this last species in the more robust make, larger scales, there being only 21 rows on the body, and larger abdominal scales especially near the head; also in the shorter triangular head, &c. &c.

I never saw it at Madras, but it is not rare at Tellicherry on the Malabar Coast. Up to 2 feet in length.

(2516) *HYDRUS GRACILIS*, Shaw—Russell 2, pls 7 and 8.

The number of rows of scales varies from 26 to 35 on the neck, and from 44 to 51 on the trunk. Scutæ 350 to 450. Scutellæ 50 to 60. Very common at Madras.

Very remarkable for the small circumference of head and neck compared to that of the body.

Very common at Madras. Up to 4 feet long.

All the above sea-snakes are venomous, and their bite to be dreaded.

### FAM. BOIDÆ—Bon.

(2517) *ACROCHORDUS GRANULATUS*, (Schneider)—A. *FASCIATUS*, Shaw.

Rare—Found sometimes in back-waters.

(2518) *PYTHON MOLURUS*, (L.)

P. *Trivittatus*, Schl.—Russell 1, pl. 22.

Boa, or Rock snake, of Europeans in Madras.

Found all over the country. I have not seen a specimen longer than 19 feet. This was killed in Travancore, after having swallowed a doe spotted deer.

(2519) *BOA (GONGYLOPHIS) CONICA*, Schl.—Russell 1, pl. 4.

Not rare in the Carnatic and Malabar. It is considered venomous by some of the natives. Has a very malignant aspect. Up to 18 inches long and upwards.

(2520) *XENOPELTIS? TRIVIRGATUS*...n. s.

Brown above, with a triple series of black marks—beneath white, black-banded; of a shin-

ing nacreous lustre throughout. Scutæ 137. Scutellæ 29. 13 rows of scales. I have only found this on the Neelgherries.

(2521) *TORTRIX ERYX*, Schlegel—var.?

Two headed snake of many:—common. Scutæ 205. Scutellæ 36.

• (2522) *CYLINDROPHIS MACULATUS?*? This, Dr. Kelaart has sent to the Society's Museum from Ceylon.—*Cur. As. Soc.*

(2523) *CYLINDROPHIS CURTICEPS*—n. s.?

Differs from the last in its shorter, more triangular head, &c. &c.

(2524) *CYLINDROPHIS MACROSCELIS*—n. s.?

Differs from both in the much larger scales. These last 3 small species are not very common. They are sometimes found on the surface of the ground in rainy weather, but are generally dug out of the earth. They are called earth-snakes by the natives.

### FAM. TYPHLOPHIDÆ.

(2525) *PILIDION? MONTANUM*—n. s.?

Above bluish-black, yellow on the sides, with a black spot on each of the 3 lower scales; abdomen banded black and white. Scutæ? Scutellæ 15. 15 rows of scales. 15 inches long. Found only on the Neelgherries.

(2526) *UROPELTIS CEYLONICUS*.

*Uropeltis affinis*—n. s.

Differs from the last in its smaller scales, in the abdominal scutæ being larger, and commencing sooner.

They are both rare. I procured them on the Western Coast.

(2527) *ONYCHOCEPHALUS ACUTUS*—Dum. et Bibr.

I possess one example of this curious reptile, which I procured in the Carnatic at Nellore. Dr. Cantor remarks, "Described from an unique specimen, habitat unknown."

(2528) *TYPHLOPS BRAMINUS*, (Daud.)—Russell 1, pl. 43.

This group, the *ARGYROPHIS* of Mr. Gray, requires to be studied, as several species appear at present to be confounded. The Society's Museum has lately received *TYPHLOPS RUSSELLII*, Gray, from Chye-basa.—*Cur. As. Soc.*

Common under stones in the rainy season, usually called earthworm.

(2529) *CALAMARIA SAGITTARIA*—Cantor.

A specimen sent to Dr. Cantor was so named by him; it had only 170 scuta and 70 cutella. It is not rare in forests in Malabar.

(2530) *CORONELLA TENIOLATA*—Russell 1, pl. 19?

15 rows of smooth scales; Scutæ 185. Scutellæ 41.

This species is referred to *Tropidonotus stola-*

# REPTILES OF THE

by Cantor, but a snake that I possess and which answers tolerably well to Russell's description and figure appears to be a true *Coronella*. It is common at Madras.

(2531) *XENODON VENUSTUM*, n. s. ? [*X. purpurascens*, Schlegel].

Above olive-brown with a triple series of irregular black spots, the central one edged with pale yellow; some transverse marks on head and neck. Has 17 rows of scales. Scutæ 142. Scutellæ 31.

Rare—found on the West Coast only; 1 foot long.

(2532) *XENODON DUBIUM*—n. s. ?

Of the pale earthy brown colour, lighter on the side; a series of darker marks, irregular in shape, and edged with black. Scutæ 181. Scutellæ 41. Has 15 rows of scales. Rare—I procured it in N. Canara.

(2533) *LYCODON RUSSELLII*—Russell 1, pl. 35.

Scutæ 193. Scutellæ 47. 17 rows of smooth scales. Rather common in Southern India.

(2534) *LYCODON AULICUS*, (L.)—Russell 1, pls. 16 and 26.

Has 17 rows of scales. My specimens have only from 165 to 174 scutæ and from 54 to 61 scutellæ, which correspond with Russell's nearly, viz. from 171 to 174 and 40 to 41, whilst Cantor gives from 208 to 257 and from 57 to 91. One specimen which resembles in colour Cantor's var. B. (*Lycodon capucinus*, Boie,) does not differ in number of the scutæ, &c. Very common all over the country, often called Carpet Snake and considered dangerous, though of course harmless.

(2535) *LYCODON PLATURINUS*, (Shaw.)

Scutæ 183. Scutella 76. Rare in Southern India—17 rows of scales.

(2536) *LYCODON NYMPHA*—Russell 1, pls. 36 and 37. bad figure.

13 rows of scales; Scutæ 234. Scutellæ 87—not rare at Madras.

(2537) *LYCODON ASSIMILIS*—n. s.

Very similar in colour to the two last species, viz. black with white bands. It differs in having 23 rows of scales. Has 190 scutæ and 60 scutellæ. I have mislaid the locality of this species.

(2538) *COLUBER BLUMENBACHII*, Schleg.—Russ. 1. pl. 34.

*Dhamin*, H., *Sarray pambou*, Tam.

Perhaps the most common snake in India, grows to a large size, 7 feet and upwards; frequents chiefly marshy land, paddy-fields, &c. Scutæ 200, Scutellæ 125—17 rows of scales.

(2539) *COLUBER FASCIOLATUS*, Shaw—Russell 1, pl. 21.

Scutæ 200. Scutellæ 58. Not uncommon at

Madras and elsewhere in the Carnatic. I have seen it nearly 3 feet long.

(2540) *COLUBER PICTUS*, Daud. Russell 1, pl. 29.

Scutæ 202. Scutellæ 91—Russ.

## ARBOREAL.

(2541) *DIPSAS TRIGONATA*—Russell 1, pl. 15.

*Tati kattaday*, Tel.; *Peri Surutay*, Tam.

Scuta 335. Scutella 83. Common in the Carnatic.

(2542) *DIPSAS CYNODON* ?

My specimens correspond very well with the description in Schlegel. Scutæ 240. Scutellæ 110. Rows of scales 21.

Up to — feet and upwards in length. I have only found this snake in forests on the West Coast.

(2543) *LEPTOPHIS PICTUS*, (Gmel.)—Russ. 1, pl.

*Kumberi mukar*, T.; *Chettooriki pambu*, Tam.

176 scutæ and 140 scutellæ—15 rows of scales. Very common in all parts of the country.

(2544) *LEPTOPHIS* ? *BELLII* ?—n. s.

Scutæ 173. Scutellæ 64. Green above, with dark line on the sides bordered on each side by a pale stripe—17 rows of scales. This much resembles the drawing of *Ahaetula Bellii* in Gray and Hardwicke. I procured one specimen in a grassy plain at Jalnah. It had killed and was swallowing a small *Vipera echis*.

(2545) *LEPTOPHIS ORNATUS*, Shaw.—Russ. 2, pl. 2.

Scutæ 209. Scutellæ 129—17 rows of scales. I have only procured this very handsome snake lately in Malabar.

(2546) *LEPTOPHIS* ? *NILAGIRICUS* ?—n. s.

Green above, yellow beneath. Scutæ 140. Scutellæ 73—13 rows of scales. Very common on the grassy hills of the Neelgherries.

(2547) *LEPTOPHIS* ? *CANARENSIS* ?

Green above, yellowish beneath with a streak on the sides. Scutæ 140. Scutellæ 57—15 rows of scales. Procured in North Canara.

Perhaps these two last belong more properly to *Dryinus*. Of the last Dr. Cantor remarks "Apparently *Dryinus Prasinus*, var. A."—the number of the scutæ, &c. however differs very materially.

(2548) *DRYINUS NASUTUS*.—Russell, 1. pl. 12

Green whip-snake. Scutæ 180; Scutellæ 158. Common all over the country. I lately saw one that had swallowed a Parroquet and became gorged.

(2549) *HERPETODRYAS MALABARICUS*,—n. s.

Olive brown with a dark streak along the sides, most conspicuous on the posterior portion of the body; a series of white spots on the anterior

# PENINSULA OF INDIA.

portion of the body, edged with black. Scutæ 222; Scutellæ 91--25 rows of scales. It is possible that this may be *H. helena*, as I possess a young one in which the markings differ somewhat, and much resemble those on Russell's figure, which is evidently a very bad one. I have procured it in Malabar where it is not very rare. [COLUBER HELENA is quite distinct.—*Cur. As. Soc.*].

(2550) *TROPIDONOTUS STOLATUS*, (L.)—Russell 1, pl. 10 and 11.

Scutæ 146; Scutellæ 61--19 rows of scales. Seldom exceeds 18 inches in length; one of the most common snakes in India.

(2551) *TROPIDONOTUS SCHISTOSUS*, (Daud.)—Russell 2, pl. 4. Scutæ 140; Scutellæ 85--17 rows of scales.

(2552) *TROPIDONOTUS PLUMBICOLOR*, Cantor. The colour of the living snake is leek green. Scutæ (in a young one) 143; Scutellæ 36?—21 rows of scales.

Found in the Wynaad [also in Bundelkund, and about Midnapore].

(2553) *TROPIDONOTUS MONTICOLUS*,—n. s. Green, with a series of dark spots on the trunk, one on the centre of back and another on each side, the one on the right somewhat in front, the left one posterior, some white marks on the head; Scutæ 132; Scutellæ 85--19 rows of scales; eyes large; 3 feet and upwards in length. Common in the Wynaad, (2 anterior frontals, 3 posterior ditto, lowest scales rhombic).

(2554) *TROPIDONOTUS PISCATOR*.—Russell, 23 and 33.

19 rows of scales; 139; Scutæ Scutellæ 83. Found in wells and tanks. Very common.

(2555) *HOMALOPSIS RHYNCHOPS*, (Schneider).—Russell 1, pl. 17

Scutæ 146; Scutellæ 65. Common in estuaries.

(2556) *HOMALOPSIS ENHYDRIS*, (Schneider).—Russell 1, pl. 30.

Scutæ 150; Scutellæ 58. Found in the same localities as the last.

## BATRACHIDÆ.

(2557) *CÆCILIA OXYURA*,—Dum and Bibr. Found on the West Coast, but rare.

(2558) *EPICRIUM GLUTINOSUM*, (L.).

Found in Malabar. 2 cirri quite distinct [Probably a distinct species from *E. GLUTINOSUM* of Ceylon, as sent by Dr. Kelaart. The latter has a strongly marked pale lateral band, and the *cirri* are less developed than they are represented to be in Mr. Jerdon's drawing. Dr. Kelaart, however, obtained a second species, and which may be that noticed by Mr. Jerdon; and either may be identical with the *Epicrium* from Assam and from Pinang—*Cur. As. Soc.*].

(2559) *RANA TIGRINA*. Bull frog. Found all over India.

(2560) *RANA CUTIPORA*,—Dum and Bibr.

In tanks in the Carnatic. Of a beautiful grass green colour, with or without a central yellow stripe on the back.

(2561) *RANA LESCHENAULTII*, Dum. and Bibr. The common frog of India.

(2562) *RANA CRASSA*,—n. s.

Of a thick clumsy form, feet webbed to the extremity of the toes; limbs shorter than in *R. Leschenaultii*, head wider, greenish above with dusky markings. Length  $3\frac{8}{10}$ ths; hind leg  $5\frac{1}{2}$ . Rare—Found in a few tanks in the Carnatic.

(2563) *RANA MALABARICA*.

Found only the West Coast, and chiefly during the monsoon when it enters houses, and makes a great gobbling, so much like a turkey that some people call it the 'Turkey frog.'

(2564) *RANA FLAVESCENS*,—n. s.

Of a buff colour on the back; yellow on the sides; limbs banded; feet webbed nearly to the extremities. Length of one  $3\frac{2}{10}$ ths; hind leg  $5\frac{1}{2}$ . Of slender make, pointed muzzle.

Found frequenting mountain streams in the forests only.

(2565) *RANA CURTIPES*,—n. s.

Head very wide; muzzle obtuse; limbs rather short; feet webbed to the ends of the toes, except the centre one. Head and back above bright buff; sides deep maroon; legs dark purple with a few white spots; abdomen white mottled. Length of one  $2\frac{9}{10}$ ths; hind leg  $4\frac{1}{10}$ th.

Found in forest only. Has a very peculiar, rather pleasing call. Chiefly seen during the monsoon.

(2566) *RANA AGRICOLA*,—n. s.

Feet not webbed quite to the extremity. Of a greenish colour, mottled with darker. Length of one  $2\frac{1}{10}$ th; hind leg  $3\frac{3}{10}$ ths; foot 1.

Found in inundated paddy-fields and meadows.

(2567) *RANA NILAGIRICA*,...n. s.

Very much allied to the last, differs in its much longer limbs. Length 2 inches; hind leg  $3\frac{8}{10}$ ths.

I have only seen this frog in marshes in the Wynaad and Neelgherries.

(2568) *POLYPEDATES LEUCOMYSTAX*.

'Chunam frog' of Europeans. Very common all over India.

(2569) *POLYPEDATES VARIABILIS*,—n. s.

Green frog of the Neelgherries.

Green, sometimes unspotted, at other times with gold spots or blackish spots; at times golden yellow with brown spots; at other times brown with darker spots.

# REPTILES OF INDIA,

Length  $2\frac{1}{2}$  inches; hind leg 4; foot  $1\frac{2}{10}$ ths.  
Found in the Neelgherries in the banks of streams and in shrubs.

(2570) *IXALIS? GLANDULOSA*,—n. s.

A small tree frog, with very obtuse muzzle, feet slightly webbed; abdomen largely glandular, tympanum indistinct; green above, yellowish on the sides and limbs.

Length  $1\frac{2}{10}$ ths; hind leg  $\frac{7}{10}$ ths; foot  $\frac{9}{10}$ ths.

(2571) *RHACOPHORUS REINWARDTII*,—Dum. and Bibr.

Found in the Malabar Coast on trees, and in grass during the monsoon. Not very common.

(2572) *LIMNODYTES? PHYLLOPHILA*,—n. s.

A small frog, with the subdigital disks very slightly dilated; toes not quite completely webbed; tympanum small; reddish yellow, with the side of the face dark purple. Length  $1\frac{1}{2}$ ; hind leg  $1\frac{2}{10}$ ths; foot  $\frac{1}{2}$ ths.

Found in all the Western forests among decayed leaves.

(2573) *PHYLLOMEDUSA? TINNIENS*,—n. s.  
Tinkling frog of the Neelgherries.

Fingers opposable; feet webbed at base only; yellowish red, or sometimes blackish above; side of head dark; inner fingers yellow; length  $1\frac{1}{10}$ th; hind leg  $1\frac{3}{10}$ ths.

Found in grass and among bushes on the Neelgherries. Has a peculiar loud clear metallic tinkling call.

(2574) *PHYLLOMEDUSA? WYNAADENSIS*.

Somewhat allied to the last, differs in its larger limbs; larger tympanum, &c. Length about 1 inch. In this when the hind leg is drawn forwards, the end of the tibia reaches the muzzle; in the last it only reaches the tympanum; reddish brown above, limbs barred.

(2575) *POLYPEDATES? SAXICOLA*,—n. s.

A small frog with teeth, tympanum distinct, fingers webbed at the base; toes webbed to the extremities; pointed muzzle; dark olive green with dark marbling, and barred limbs. Length  $1\frac{1}{10}$ th; hind leg  $1\frac{3}{4}$ th; foot  $\frac{5}{10}$ ths; femur and tibia reach beyond the muzzle.

Found on rocks in shady mountain streams in Malabar and Wynaad.

(2576) *HYLÆDACTYLUS MONTANUS*,—n. s.

Mottled green and brown above. Length  $1\frac{7}{10}$ ths; hind leg 2; foot  $\frac{7}{10}$ ths. Hab. Mountain streams in Wynaad, rare. [A very nearly affined species, if not the same, inhabits Mergui].

(2577) *HYLÆDACTYLUS CARNATICUS*,—n. s.

Of small size; marbled green and brown; muzzle more acute than in the last species; length  $1\frac{3}{10}$ ths; hind leg  $1\frac{3}{10}$ ths; foot  $\frac{5}{10}$ ths. Found in the Carnatic during the monsoon, rare.

(2578) *BUFO SCABER*, Daudin.

Common toad of India. Very abundant.

(2579) *HYPERODON MARMORATUM*.

Found in the Carnatic during the monsoon.

(2580) *PYXICEPHALUS FODIENS*,—n. s.

Greenish marbled with brown. Length 2 inches; hind leg  $2\frac{3}{10}$ th, foot  $\frac{8}{10}$ ths. Found in the Carnatic, burrows in the ground for  $1\frac{1}{2}$  feet or so. [Hab. also Ceylon].

(2581) *PYXICEPHALUS PLUVIALIS*,—n. s.

Nearly allied to the last; differs in its shorter thicker form, and shorter limbs; light greenish fawn, with dark marbling. Length of one  $2\frac{2}{10}$ ths; hind leg  $2\frac{4}{10}$ ths; feet  $\frac{8}{10}$ ths. I only procured this during the monsoon in the Carnatic. It is very different in appearance, though with so few essential distinctions, and the natives give a distinct name to each.

(2582) *PYXICEPHALUS RUFESCENS*,—n. s.

Of a rufous colour above, whitish beneath; body rough and granulose; limbs barred.

Length  $1\frac{1}{2}$  inch; hind leg  $2\frac{1}{10}$ th; foot  $\frac{6}{10}$ ths. Not rare in gardens on the Malabar Coast.

(2583) *ENGYSTOMA ORNATUM*.

Some specimens of this very handsome frog were only once procured by Walter Elliot, Esq. on the Neelgherries.

Length  $1\frac{4}{10}$ ths inch, hind leg  $1\frac{6}{10}$ ths; foot  $\frac{11}{10}$ ths.

(2584) *ENGYSTOMA RUBRUM*,—n. s.

Indian red above; some black marks on the leg. Length  $1\frac{1}{10}$ ths inch; hind leg  $1\frac{5}{10}$ ths; foot  $\frac{5}{10}$ ths.

Found in the Carnatic near rivers, in sandy banks. Also Ceylon.—*Cur. As. Soc.*

(2585) *ENGYSTOMA MALABARICUM*,—n. s.

Isabella colour above, varied with dark angular markings; sides dark purplish; throat ditto; limbs barred. Length  $1\frac{1}{10}$ th; hind leg  $1\frac{6}{10}$ ths; foot  $\frac{5}{10}$ ths. Found in Malabar, under stones.

(2586) *ENGYSTOMA CARNATICUM*,—n. s.

Nearly allied to the last; differs in the shorter muzzle, shorter hind leg, &c. Length  $\frac{9}{10}$ ths of an inch; hind leg  $1\frac{1}{10}$ th; foot  $\frac{4}{10}$ ths. Found in the Carnatic during the monsoon.

*Reptiles, new or little known, By E. BLYTH, Beng. As. Soc. Journ. No. 7 of 1853 p. 639 to 655.*

(2587) *TESTUDO PHAYREI*, Blyth.

Great Burmese land Tortoise.

Carapax smooth, as in *T. RADIATA* and *T. ANGULATA*, but much flatter; oblong, subquadrate, its free marginal plates reverted and moderately serrate. Nuchal plate broader than long. Caudal plate double. Gular plates longer than broad, moderately notched; broader

than long, and deeply notched. Back unmarginate. Fore-limbs covered with very long and thick imbricated scales, much as in a Pangolin; the claws elongate, strong and thick: similar great elongate scales at the heel; and a group of five principal obtuse spines on either side of the tail, the medial of them remarkably strong and thick. Two or more smaller spines or thick elongate scales above the tail. Colour wholly black, or mingled more or less with buff-yellow. In the young, the scales are probably of the latter hue, with gradually increasing black centres. Limbs deep brown; some of the claws yellow in some specimens: the head and neck paler brown, strongly tinged with yellow. Our largest specimen is 20 in. long in a straight line, or  $22\frac{1}{2}$  in. measured over the curve of the carapax, from front of nuchal plate to middle of caudal notch: greatest breadth  $14\frac{1}{2}$  in. or  $20\frac{1}{2}$  in. following the curve, from one obtuse lateral angle to the other. Height  $1\frac{1}{2}$  in. Head to occiput  $4\frac{1}{2}$  in. The shell of this individual is wholly black, with merely a few slight indications of the ochreous yellow colouring: all the claws deep brown. Another, rather smaller, has the appearance of great age, with most of the plates of its carapax more or less completely united, so that the form of some cannot be traced. Colour irregularly mingled black and dull buff-yellow; the plastron chiefly black; and several of the claws are yellow wholly or in part. Hab. Arakan; Tenasserim Provinces. Specimens presented by Capt. Phayre.

(2588) *TESTUDO ELONGATA*, Blyth.

Small Burmese land Tortoise.

Carapax elongate, becoming more so and quite smooth in adults, wherein it approaches to a semi-cylindrical form; flattish, sub-even, the three medial vertebral plates lying almost in a plane, and the free marginals slightly reverted. Caudal broader than the last vertebral. Nuchal twice or thrice as long as broad, and even with the borders of the anterior marginals. Gulars not notched, or but very slightly so. Caudals divergent from base, and transversely elongate-triangular, broader than long, forming a slight lateral notch with the ventrals. Beak laterally notched or distinctly three-pointed. Scales of the limbs rather small, contrasting much with those of the preceding species. Colour of half grown specimen orange yellow, each plate having a large black centre, which mostly disappears with age, leaving a few more or less radiating black spots on those of the carapax, and often a black spot on only the large medial plates of the plastron. Head and limbs brown, much tinged with yellow. Length of an adult 13 in. in a straight line, by 8 in. across, or rather more towards the hinder part of the body. Height  $5\frac{1}{4}$  in. Head to occiput  $2\frac{3}{4}$  in. Hab. Arakan. Specimens presented by Capt. Phayre. According to Dr. Helfer, Tortoises abound in

the Tenasserim Provinces, and are much eaten by the Peguers and Karens, who train dogs to search for them.

(2589) *TESTUDO STELLATA*. In India proper and also in Ceylon, only one species of land Tortoise occurs, the *T. Stellata*, Schweigger, a figure and interesting notice of which are given by Capt. Hutton in *J. A. S.* VI, 689, under the supposition of its being *T. Geometrica*. The latter is a S. African species, very similar to *T. Stellata*, but having a distinct nuchal plate, which *T. Stellata* does not possess, and exhibiting certain other distinctions. Among some Tortoises, however, presented to the Society by Capt. Sherwill from S. Africa, are two small specimens of *Geometrica*, and one full grown example which can in no way be distinguished from the Indian *Stellata*. The latter does not inhabit Lower Bengal, and is rarely brought alive to Calcutta. One much more commonly brought here is the *T. Radiata*, Shaw, a larger species remarkable for its very hemispherical form, and which is said to be indigenous to Madagascar, in which case it is probably brought to India from the Mauritius. The very large specimen referred by Mr. Blyth, to *Stellata* (*v. actinodes*) in a note to p. 462 *ante*, he now thinks, after much consideration, to be distinct, and indicates as

(2590) *TESTUDO MEGALOPUS*, Blyth *n. s.*

Similar to *T. Stellata*, but attaining a much greater size, with proportionally much larger feet and claws. The colours duller and therefore less strongly contrasting, and the lines radiating from each boss of the carapax more numerous. Fore-feet with two large claw-like scales of equal size behind the palm, and no others approaching them in size. Claws of hind-feet fully twice as large as in adult *Stellata*. Length of carapax, measured in a straight line, 12 in. by  $7\frac{1}{2}$  in. in diameter breadth. Hab.—?

There are several living specimens about Calcutta, of the great Seychelle Tortoise, miscalled *T. Indica* by Gmelin, and under which Mr. Gray unites no fewer than seven of the supposed species admitted by M.M. Dumeril and Bibron. According to Dr. Schlegel, "The Indian Tortoise [so-called], probably indigenous to Madagascar and the neighbouring isles, has been acclimated in the Gallapagos Isles, in California, and on several other points on the western coast of South America:" but we have been assured, on good authority, that numerous specimens kept in gardens in the Mauritius, have all been brought from the Seychelle Islands in the first instance, that they are still commonly brought from those islands to the Mauritius, and thence we believe the few in India have been imported. It is most assuredly not an Indian reptile, nor have we heard of its ever propagating in this country. In the Mauritius he is informed that it is eaten. The largest he has

seen is in his own possession, alive, and measures 4 ft. 4 in. in length over the curve of the carapax, or 3 ft. 5 in. in a straight line; transversally 4 ft. 2 in. over the high arch of the carapax, or in a diameter line 2 ft. 2 in. in height, when not raised upon the legs, i.e. height of shell,  $20\frac{1}{2}$  in.; when walking, the shell is lifted fully 6 in. from the ground, if not more: circumference of hind-foot  $7\frac{1}{2}$  in. He continues:—A scientific friend, recently from Jamaica, assures him that this great Seychelle species is quite distinct from the great Gallapagos Tortoise, which has bred and multiplied in Jamaica and other W. Indian islands. Curious, that these gigantic land Tortoises (diminutive, however, in comparison with the extinct Indian *Colossocheilus*), should thus be indigenous to small oceanic groups of islands, in each case remarkable for the peculiarities of both their *fauna* and *flora*. We are reminded of the great wingless birds (Dodos and Solitaires) of the Mauritius, Bourbon, and Rodrigues; those also of N. Zealand and of Madagascar; the Megapodius of the Nicobars, and its congeners of other islands; the singular and quite recently extinct grey Parrot of Philip Islet near Norfolk island, with its sole congener in N. Zealand; the Owl-like nocturnal Cockatoo of N. Zealand, also close upon extirpation, &c. The majority, if not all, of these islands appearing to be remnants of what may be comparatively termed continents, each with its peculiar centre or centres of creation.

In all these supposed reliques of ancient lands, with the chief exception of Madagascar, mammalia are rare, and are chiefly or wholly *Cheiroptera*, *Rodentia*, and *Marsupialia*; the two former orders comprising the only placental mammalia of Australia; and one species of each of these placental orders being the only known indigenous mammals of N. Zealand, though a large Badger-like animal has lately been reported in the latter country, in all probability a marsupial. Madagascar is very remarkable for the extraordinary development of the quadrumanous group of Lemurs, among the higher placental mammalia; and has even a rodent Lemur in *Cheiromys*, as Australia has a rodent marsupial in *Phascalomys*. Its other placental mammals are mostly of peculiar genera, unknown even on the neighbouring continent of Africa; and no marsupial has been discovered there.

From Afghanistan Mr. Gray describes a *T. Horsfieldi*, which he suggests may be *T. Iberia*, Pallas, *Faun Casp.*, t. 5. The Society's Museum possesses a land Tortoise from that country, which however belongs to the genus *Homopus*, having but four claws to each foot. It may be thus described.

(2591) *HOMOPUS BURNESII*, Blyth. Carapax squarish, depressed, broadest posteriorly, where the free marginals are a little reverted and distinctly serrate. Anterior border straight, the

nuchal plate well developed. Caudal as broad as the last vertebral, and broader than the other vertebral plates. Nucleus of each lateral or discoidal plate near its inner or upper border. Gular plates longer than broad, the two forming a nearly equilateral triangle. Anals oblong, divergent, forming a rather deeply notched border. Scales of fore-limbs rather large, and those to the front mostly uniform in size. Claws elongate, or not worn down by attrition. Beak three-pointed. Colour yellow above, with black nuclei to the plates: those of the plastron black with yellow border. The head and limbs appear to have been yellowish. Length of carapax 6 in., by  $5\frac{1}{4}$  in., measuring straight. Height  $2\frac{7}{8}$  in. Head to occiput  $1\frac{1}{2}$  in. This large specimen was procured in Afghanistan by Sir. A. Burnes.

A very small *Homopus* in spirit, also from Afghanistan, is doubtless the young, though exhibiting some remarkable differences in the shape of the upper plates. In this the nuchal is roundish, or as broad as long; and all the vertebrals are about equally broad. Colour dull yellow throughout. Presented to the museum by Dr. Allan Webb.

(2592) *EMYS*. Of the numerous true *Terrapins* (*EMYS*) of the Gangetic rivers, only three species are common in the vicinity of Calcutta; and adults of all are rarely met with. These are—

(2593) *EMYS THURGII*, Gray, which attains to a much larger size than has hitherto been described, adults measuring 20 to 22 in. (straight) in length of carapax

(2594) *EMYS TECTUM*, Gray, the adults of which measure similarly 6 in.; and

(2595) *EMYS HAMILTONII*, Gray, the adults of which measure similarly  $5\frac{1}{2}$  in. The only other species we have yet met with from this vicinity is

(2596) *EMYS TENTORIA*, Gray, one young specimen only. This Mr. Gray describes from the Bombay Dukhun, where procured by Col. Sykes; and Sir Alexander Burnes obtained an adult from the Indus, which is now in the Society's museum. These two specimens differ in some respects from each other, also from Mr. Gray's description, and from Buchanan Hamilton's coloured figure, the two latter again presenting certain discrepancies one from the other. The species is nearly affined to *E. Tectum*, Bell, but at all ages has the median keels to the first three vertebral plates much less developed, and the form of the whole carapax is conspicuously flatter and broader. A peculiarity of both species consists in the peculiar decanter-shaped form of the fourth vertebral plate. Comparing the adult of *E. Tentoria* from the Indus (length of carapax, measured straight,  $6\frac{3}{4}$  in.) with an adult of *E. Tectum* from the Hughly (carapax, similarly measured, 6 in.), the first ver-

tebral plate is proportionally much broader in the former, pentagonal, narrower to the front, with a broad straight transverse base posteriorly, and the keel little developed; whereas the first vertebral plate of *E. Tectum* is pentagonal, broader to the front, with a rounded posterior base, and much more developed keel. In the former, the first vertebral is considerably larger and somewhat broader than the second, whereas in the latter it is sub-equal or even rather smaller than the second: in adult *E. Tentoria* the second vertebral plate is hexagonal but almost square, and rather broader than long, with the keel nearly obsolete: in *E. Tectum* somewhat pear-shaped, truncate to the front and narrowing and curving off posteriorly, with the keel strongly marked: the third vertebral plate of adult *Tentoria* is quadrangular, longer by half than broad, with the keel quite obsolete on the anterior half, and flat and but little raised posteriorly; in *E. Tectum* it is hexagonal, with the keel strongly developed and prolonged backward. A narrow black line is continued along the spinal ridge of *E. Tentoria*; whereas the middle of the ridge is broadly white in *E. Tectum*, bordered by a black line on either side. The plastron of *E. Tentoria* is blackish-brown, with a pale border to each plate; in *E. Tectum* pale with two or three distinct blackish patches on each plate. Comparing the young of the two species, the first vertebral plate forms a much broader pentagon in *E. Tentoria*, being equal in breadth to the second; in young *E. Tectum* the first vertebral plate is considerably narrower than the second: the second vertebral plate in young *Tentoria* forms a heptagon with the base posteriorly; in young *Tectum* a pentagon with rounded apex and anterior base: the third in young *Tentoria* is subquadrilateral, somewhat longer than broad, with the keel a little produced posteriorly; in young *Tectum* a pentagon with its base to the front, and the keel much broader and more prominent. Yet, notwithstanding these great differences of detail, and also of the colouring of the head, neck and limbs, the two species are very liable to be confounded on a superficial glance.

According to M.M. Dumeril and Bibron, the *E. Trijuga*, Schweigger, was obtained by M. Duvaucel from the "salt-water lake" lying east of Calcutta; but of the numbers of *Terrapins* which we have seen from that locality, we have sought in vain for this species, which belongs to the peninsula of India, and is the only one which has been there observed, with the exception of Col. Sykes's specimen of *E. Tentoria*. In Ceylon it is replaced by the very distinct *Emys sebæ* Gray.

(2597) *EMYS DHONGOKA*. Since the above was printed, we have obtained another *Emys* from the vicinity of Chaibasa, which appears to be the young of *E. Dhongoka*; and Mr.

Jerdon assures that a large species abounds in the Nerbudda, two feet and upwards, which is probably the same: it is not referred to in Mr. Jerdon's paper, p. 463 *ante*

On the Arakan coast, adults of *E. Dhongoka*, Gray, approaching to 2 ft. in length of carapax, would appear to be very common; but the only young specimen which we have seen of this species was sent down alive from Asam by Major Jenkins, and is now mounted in our museum. The adults have much the appearance of *Tetraonyx Lessonii*, D. and B., but are readily distinguished by having five instead of four claws to the fore-feet.

(2598) *TETRAONYX LESSONII* abounds at the mouth of the Hugly, and great numbers are brought to Calcutta, where they are eaten by particular castes of Hindus, and are even kept for sale in tanks. Though the water-Tortoises generally are much used as food, the species chiefly consumed, or at least which are brought in greatest quantity for that purpose, are *Tetraonyx Lessonii* and *Emyda Punctata*. The latter appears to be the most generally diffused species of Tortoise throughout the whole of India and Ceylon, and is very abundant in Lower Bengal, burrowing deep into the beds of tanks when the water dries up. A large one which escaped into the Society's compound was found several months afterwards in a healthy state, buried among the roots of some guinea-grass.

A small and evidently young *Emys* from Arakan or Tenasserim would seem to be

(2599) *EMYS OCELLATA*, Dumeril and Bibron. The colouring agrees with the description: the details of structure less completely. Length of carapax 6 in. (measured straight). It is affined to *E. thurgii*; and as compared with a specimen of *E. thurgii* of the same size, it is at once distinguished by having the whole under surface of the shell spotless yellowish-white, and each lateral or discoidal plate of the carapax is marked in the centre with a large round reddish-brown spot, surrounded by a pale areola; an interrupted black line along the spinal ridge, which is raised into keels on the first four vertebral plates. These are of equal breadth, whereas in *E. thurgii* the first is much narrower than the others. Nuchal plate twice as long as broad, and throughout equal; whereas in *E. thurgii* it is triangular with posterior base. Hindmost vertebral plate much narrower than in *E. thurgii*; and the posterior marginals and especially the caudals are much smaller than in that species. Colour of the upper parts greenish olive-brown, with the ocelli before mentioned, will probably become obscured with age. Head brown above, with yellow superciliary line meeting its opposite over the nostrils,

## REPTILES OF INDIA,

Limbs and under parts apparently yellowish without markings.

There is a species of Chameleon in the Society's old collection, the origin of which is unknown, but it would appear to be undescribed. It would seem to be most nearly allied to *C. cucullatus*, Gray, and has the occipital flaps of both that species and *Ch. delepis*, Leach.

(2600) *CHAMELEON VERRUCOSUS*, Blyth. Body minutely tuberculated, with large tubercles regularly interspersed throughout. The latter are smaller and contrast less strongly on the limbs and tail, and are more thickly set upon the limbs. Ridges of the back and throat serrated, the tubercles becoming smaller towards and upon the tail. Beneath, the tail is smooth, though tending to exhibit a slight serrature towards its base. Superciliary ridges not uniting together, either before or behind; and a small medial occipital ridge continued to the base of the two lateral flaps or lappets of skin. Colour of the specimen blanch- ed; but there is a strongly marked black streak proceeding backward from the axilla, and sur- mounted by a white streak, the two occupying the space which may be concealed behind the humerus. Length  $11\frac{1}{2}$  in., of which the tail is 6 in. Hab. unknown.

(2601) *LEIURUS BERDMOREI*, nobis (*Geck- oide*). Agrees with Mr. Gray's definition of *Lei- urus*, except that there is no appearance of the toes being webbed at base. Colour grey, with 4 longitudinal blackish streaks along the back and sides, 3 or 4 interrupted crossbands of the same on the upper surface of the tail, a medial black streak on the nape, and others successively diverging on each side of it, and a black streak from before the eye continued to the shoulder. Some mottling also on the limbs. Hab. Mergui, where procured by Capt. Berdmore.

(2602) *STELLIO*. The genus *Stellio* is new to the Indian fauna. A species from Upper Hindu- stan cannot be safely separated from the Arabian *St. Cyanogaster*, Rüppell, unless upon compari- son of specimens. The tail, however, appears to be longer; and there is a slight gular fanon. Spe- cimens very much in colour. An adult from Mir- zapore, presented by the late Major Wroughton, measures  $12\frac{1}{2}$  in. long, of which the tail is 8 in. Throat blue, spotted over with yellowish-white, deepening to purple on the *Fanon* which is less spotted. The rest of the lower parts are yellowish- white, marbled on the transverse fold of the neck and immediately behind it with blackish, and spotted with the same on the breast and belly, the spots becoming less numerous on the latter. Upper parts dark olive-green, the back and sides speckled over with whitish. Two smaller speci- mens were presented to the Society by L. C. Ste- wart, Esq., now of H. M. 61st Regt., from Wuzcerabad. Length of one  $8\frac{1}{2}$  in., of which the

yellowish-white, suffused or marbled with bluish or pale dusky on the throat, and slightly spot- ted with the same on the breast. Upper parts paler olive green than in the large specimen; the back and side speckled with yellowish-white in one, as in the adult example, with traces of dusky marbling on the back; in the other, the back is much more marbled and blotched with dusky, and has only a few largish dull white spots on the back and sides, while the limbs and tail are banded, and there are three dark transverse lines over each eye. If new, *St. indicus*, Blyth.

(2603) GENUS *CALOTES*, Kaup. We have now nine well marked species of this genus in the museum, the first three are distinguished by a pit or fold before the shoulder, which is lined with minute scales.

(2604) *CALOTES EMMA*, Gray (vide "Proceed- ings of the Asiatic Society" for May, 1853, p. 413) Inhabits Mergui, and probably other parts of Burma, ranging northward perhaps to the Khasya hills; but extremely doubtful as an inhabitant of Afghanistan. We have elsewhere expressed our suspicion (*loc. cit.*) that collections made by the late Dr. Griffith in Afghanistan and in the Khá- sya hills had become mixed and confounded, and hence that Mr. Gray had been led to assign his *Calotes Emma*, *C. Maria*, *C. Minor*, and *Salea Horsfieldi* to Afghanistan, and two of the four to the Khásyas also; countries so extremely differ- ent, that it is most improbable that the same species would be found to inhabit both of them.

(2605) *CALOTES MYSTACEUS*. Dumeril and Bibron. (Described *J. A. S. XXI*, 754). Inhabits Burma, and also the mountainous parts of Cey- lon. Hind-toe reaching to the ear.

(2606) *CALOTES ROUXI* (?), Dumeril and Bi- bron. Three adult specimens and another half grown forwarded by Dr. Kelaart from Newera Elia, in Ceylon, accord fully with the description as regards structure; but the colouring is re- markable, and different again from that of Mr. Jerdon's supposed *C. Rouxi* of S India. Pit before the shoulder more developed than in *C. Mystaceus*, and partially black. Hind-toe reaching to the eye. A row of 3 or 4 raised spines above the tympanum; and nuchal crest moderate and gradually diminishing to the tail. The latter is tumid at base, and soon attenuates rather sud- denly, the tumid portion exhibiting a median ridge of very broad keeled scales. Caudal scales towards the base of tail much larger than those of the body. Throat scales very broad and flat, with a median row of narrow compressed scales imparting the appearance of a small *fanon* or dew- lap. A half-grown specimen (in spirit) is blue, with the tail reddish-brown to near its base, and mark- ed with an irregular double series of *ocelli* which

is a black mark between the eye and the ear, and another below the eye; and a tinge of ruddy on the throat, about the tympanum, and on the occipital and tympanic spines. Adults (in spirit) have the body and limbs blue, the tumid base of tail green, and the rest of the tail dull red-brown, with *ocelli* less bright than in the young. Borders of lips black, continued as a broad black band (more or less variegated with ruddy-white) to the shoulder-pit. Throat whitish tinged with ruddy and strongly contrasting, as also a white band from the tympanum continued over and passing the shoulder-pit. In some, the shoulder-pit is also posteriorly margined with a white mark; and raising the fore-leg two or three additional white stripes are seen, oblique and successively more inclining to the horizontal. The limbs are also banded with white; but these markings are often indistinct or obsolete. Tumid base of tail bright orange underneath in some specimens. *C. Rouxi* is described from Burmah; but as we possess the preceding species both from Burmah and the mountains of Ceylon, it is the less improbable that the present may have the same habitat.

(2607) *CALOTES GIGAS*, Blyth. (Supposed *C. Ophiomachus*, *J. A. S.* XI, 870). Resembles *C. Versicolor*, except in being much larger, having no trace of gular *fanon*, and a double nuchal crest of spinelike scales,  $\frac{1}{2}$  in. long in the specimen under examination. Dorsal crest also proportionally more developed than in *C. Versicolor*, and terminating abruptly over base of tail. Length of head and body  $5\frac{3}{4}$  in. Of tail —? Of hind-limb  $3\frac{3}{4}$  in. Colour apparently uniform without markings, but the specimen is much blanched. Hab. —?

(2608) *CALOTES VERSICOLOR*, Daudin. The most common and generally diffused species, inhabiting all India and Ceylon, from the base of the Himalaya southward, and (according to Mr. Gray) also China and Afghanistan (vide, however, remarks on *C. Emma*). It is the only species we have in Lower Bengal, where it is excessively abundant, particularly in gardens. Sir A. Burnes sent a specimen from Sindh; and we have also one from Rangoon. In the last, however, the scales are somewhat smaller than in Indian specimens, and the two detached spines on the tympanic ridge are remarkably minute; but there is no other difference. Ceylon specimens, on the other hand, appear commonly to attain a greater size, with somewhat larger scales, the nuchal and dorsal crests and also the gular *fanon* being rather more developed and they are then the supposed *C. Rouxi* apud Blyth of *J. A. S.* XXI, 354; but smaller and younger specimens from Ceylon are quite undistinguishable from Bengal examples; and it may even be that the latter sometimes attain the size and general development of the Ceylon reptile. Some

living examples sent from Galle by Dr. Kelaart are quite undistinguishable from living Bengal specimens. In S. India, again, the changes of colouring (as described by Mr. Jerdon) differ from those of *C. versicolor* of Bengal, and are perhaps the same as in the Ceylon animal. Here the colors are changeable, but no yellow is ever seen; and in the months of May and June, the males chiefly are often observed with the head and anterior third of the body, inclusive also of the forelimbs, tolerably bright red, a large black patch before the shoulder, and all the rest plain greenish-brown. They are often altogether of the latter hue without markings; or the markings come out more or less strongly. The reptile is then commonly brown, lighter or darker, with a series of transverse dusky bands, broken on either side by a longitudinal whitish band which is evanescent, appearing and disappearing and sometimes shewing very conspicuously. A dusky streak through the eye, and three others radiating below and two above it. Three or four oblique streaks on each side of the throat; and others on the limbs. Females are smaller and darker, generally of the hue of the ground on which they lie.

(2609) *CALOTES VIRIDIS*, Gray. Nuchal crest extremely slight; and no decided spines above the tympanum, but three raised angular scales placed not on a ridge, but disposed triangularly and separated apart. In some specimens, probably the females, the latter are scarcely noticeable. There is also a row of five flattened scales from below the eye to above the tympanum. Two longest hind-toes of subequal length and reaching only to the ear. Body scales acutely pointed, especially those of the lower parts. Colours green or brown, mottled with whitish and with dark brown; lips black. From S. India.

(2610) *CALOTES OPHIOMACHUS*, (Merrem). Tympanic ridge with several short and two longer spines. Longest hind-toe reaching to front of eye. Tail extremely long, its terminal three-fourths commonly whitish. General colour green, paler below; with some irregular white transverse bands on the body in adults. Stripe through the eye red; and nuchal crest and throat the same in the breeding livery of the males. One Ceylon example (in spirit) is remarkable for having a longitudinal white lateral band, continued from the shoulder to the tail upon which it becomes broken and lost. Identical from S. India, Ceylon, and the Nicobar Islands.

(2611) *CALOTES PLATYCEPS*, Blyth, *J. A. S.* XXI, 354. Hab. Khásiya hills.

(2612) *CALOTES TRICARINATUS*, Blyth. Founded on a young specimen of a well marked species, affined by the flat form of the head to the last, but particularly distinguished by having

## REPTILES OF INDIA,

three low crests or keels along the nape and shoulders. An oblique row of six large triangular scales over each tympanum, but no spines (perhaps on account of youth). Longest hind-toe reaching to tip of muzzle. Colour (in spirit) blue above, white beneath. From near Darjiling, where procured by Capt. Sherwill.

(2613) *ASPRIS*, Blyth, *n. g.* (*Scincidae*). Affined to *Tropidophorus*, Dumeril and Bibron, but differs much in the arrangement of the shields upon the head, and the face anterior to the eyes is compressed and narrow, with subacute muzzle. Tongue very slightly notched. Teeth extremely minute. Frontal shield elongate-pentangular, attenuating much posteriorly: frontoparietals triangular and contiguous; parietals large subovate; interparietal smaller, elongate and obtusely pentangular; superciliaries, five in number, broad, the two series separated apart by the narrow hinder part of the elongated frontal shield. Scales of the back and upper part of tail rhombic, strongly carinate, the keels running in parallel ridges; of the belly roundish, smooth. Præanal scales 2, large, triangular. Toes 5-5, simple, slender.

(2614) *ASPRIS BERDMOREI*, Blyth, *n. s.* Colour dusky-brown or blackish, the throat and belly ruddy-white, with some cross-bands of the same upon the neck and body, broader and more distinct on the former, and white specks on the lips, chin, and on the under and lateral surface of the tail. Eight distinct rows of keeled scales along the back. Length of specimen  $4\frac{1}{2}$  in., of which the tail is  $2\frac{1}{2}$  in., and head  $\frac{9}{16}$  in.; forelimbs  $\frac{9}{16}$  in.; hind-limbs  $1\frac{1}{8}$  in. Hab. Mergui, where procured by Capt. Berdmore.

(2615) *MOCOA FORMOSA*, Blyth, *n. s.* Length of one 7 in., of which the tail measures half. Scales hexagonal, in six dorsal series. Præ-anal scales similar to the abdominal. Form robust. Frontal shield elongate-pentagonal, broadest to the front, and rounded posteriorly. Inter-nasal and frontonasals lozenge-shaped, or somewhat fan-shaped, broader than long. Frontoparietals distinct, but unsymmetrically divided. Colour olive-green, with black lateral and pale superlateral bands as usual, the former much speckled with greenish-white, and the latter shewing a series of black spots. Between the pale superlateral streaks are five narrow black lines along the nape and body, variegated with angular greenish-white spots. A few such spots appear also on the upper surface of the tail, caused by a scale variegated with black and greenish-white here and there placed. Limbs minutely pencilled with black, and spots or streaks of the same upon the head. Under-parts greenish-plumbeous throughout. This large specimen was procured at Mirzapore by the late Major Wroughton; and others from Wuzeerabad, presented by L. C. Stewart, Esq., now of H. M. 61st Regt., are

smaller and less marked with black, which does not form continuous lines along the back, but variegated scales (black, with pale medial portion,) are throughout scattered, and there are some black markings on the head.

(2616) *MOCOA SIKIMMENSIS*, Blyth, *n. s.* A small species, about 4 in. long, the tail varying in length in different individuals. In one the head and body measure  $1\frac{1}{2}$  in., the tail  $2\frac{1}{2}$  in.; in another the head and body  $1\frac{1}{4}$  in., the tail but 2 in. This difference is probably sexual, the former proportions denoting the male, and the latter the female. The same variation occurs in the species of *Riopa*, Gray. Closely affined to the preceding species, but much smaller, flatter, and more lustrous, with proportionally much more slender toes. Colour of the upper parts nacreous olive-green, with three irregular black lines or rows of specks along the back, not always very conspicuous. A broad black lateral band, becoming obsolete along the sides of the tail, is margined with a glistening pale greenish stripe above, and variegated with spots of the same along its lower half and on the outside of the limbs. Underparts greenish-white, except the tail and below the limbs where the colour is rufous-white. Some have a few dark spots on the throat.

Hab. Sikim, where procured by Capt. W. S. Sherwill.

(2617) *PLESTIODON QUADRILINEATUM*, Blyth, *n. s.* Proportions of *Tiliqua*: the head small, but its plates almost exactly as in *Pl. Laticeps* of N. America. Colour blackish above, pearly white below; two dorsal greenish-white streaks, commencing at the nostrils and gradually disappearing at about the middle of the tail; these streaks being exterior of the two alternating series of medial and hexagonal dorsal scales; also a lateral pale streak from fore to hind limb, which is more or less indicated on the neck and base of tail, close upon the whitish hue of the under-parts. Length  $7\frac{1}{2}$  in., of which the tail measures  $4\frac{1}{2}$  in., of hind-limb  $\frac{5}{16}$  in., China (Hong-Kong?). J. C. Bowring, Esq.

(2618) *EUPREPES MACULARIUS*, Blyth, *n. s.* Affined to *Eu. Cyanogaster*, (Lesson. v *Eu. sechellensis* D. & B.) Like *Tiliqua rufescens*, (Shaw), but the scales of the upper-parts 5-7 carinate, and colour bronzed olive-green above, pale below; the hinder half of back and base of tail above marked with irregular reddish-brown spots, and a broad reddish-brown lateral streak continued from the ear to the middle of the tail, marked throughout with white, which tends to form continuous lines posteriorly. Terminal half of tail whitish. Arms and hind-limbs speckled with white posteriorly. Length of specimen  $5\frac{1}{4}$  in., of which the tail measures  $3\frac{1}{2}$  in. Hab. Rungpore?

(2619) *LISONOTA*, Blyth, *n. g.* Form of *Euprepes*, but more slender, covered with very smooth minute uncarinated scales. Head short

flat, subtriangular as viewed from above, broader than high, with obtusely pointed muzzle. Tympanum distinct, roundish. Lower eyelid scaly. Palatal incision slight, placed far back. Tongue scarcely notched. Teeth very minute. Frontal shield pentagonal, subtriangular, broad to the front, and elongated to an obtuse point posteriorly; the supra-orbitals nearly meeting across. Inter-nasal hexangular, somewhat fan-shaped. Fronti-nasals small. Fronti-parietals two, contiguous. Inter-parietal squarish or diamond-shaped. Limbs well developed. Toes 5-5, the palms and the heels (or exterior portion of soles) granular. Infra-caudal scales larger than those of the body; and two large triangular præ-anal scales.

(2620) *LISSONOTA MACULATA*. Blyth. This species would seem affined to *Plestiodon sinensis*, Gray. *n. s.* Colour (in spirit) greyish olive-green, with a double row of irregular dark spots along the nape and back, and a median line of the same along the tail. On each side a dark band is continued throughout, commencing at the nostrils; and beneath this is a narrow pale streak, then a narrow dark one, and finally a few dark spots on the sides of the throat and belly. Upper surface of the limbs variegated throughout. Lower-parts albescent-greenish. Length of specimen, —head and body  $1\frac{7}{8}$  in., and tail probably about the same, but the tip is wanting. Fore-limbs  $\frac{5}{8}$  in.; hind limbs  $1\frac{5}{8}$  in.: distance apart of fore and hind limbs 1 in. From Assam Col. Jenkins.

(2621) *OPHIOPS JERDONI*. Blyth, *n. s.* A typical species, dark bronze above, black-spotted, with two obscure broad dorsal streaks; below white throughout. Length of head and body  $1\frac{1}{2}$  in., of tail  $2\frac{1}{4}$  in.; of hind-limb, to extremity of longest toe,  $\frac{3}{4}$  in. Femoral pores 7 or 8. Shields of head plaited longitudinally. "Procured at Mhow, in pasture land." T. C. Jerdon, Esq. Since Mr. Jerdon's paper on the reptiles of S. India was ready for publication. With reference to that paper, p. 463 *ante*, he desires to state that "the only specimen of *Homonota fasciata* was taken from the mouth of a snake, in grassy land, near Jaulnah."

(2622) *SPHENOCEPHALUS*, Blyth, *n. g.* A *Sepsoid* form affined to *Sphenops*, Wagler, but with more slender and elongated shape, and the limbs placed more distinctly apart; the anterior minute and fitting into a groove, the posterior as large as in *Sphenops*, and each having but three toes, of which the innermost and next are subequal and the outer much shorter. It is still more nearly affined to the Australian form *Ronia* of Gray, figured in the Appendix to Gray's Journal; but this has still more rudimentary limbs, the anterior merely indicated externally, and the posterior shewing but two digits. Form slender,  $\frac{2}{3}$  cylindrical, quite flat and laterally angulated beneath as far as the vent: the body and tail covered

with small, smooth, lustrous, hexagonal scales, with a median row of broader scales along the under surface of the tail. Head much as in *Sphenops*, but the muzzle more pointed; the upper lip covering the mouth. Tongue broad, triangular, its cleft scarcely perceptible; the incision of the plate small. Teeth very minute. Eyes minute, with semi-transparent lower lid. No external trace of ear. Nostrils terminal, placed in the anterior margin of the nasals, contiguous to the front of each inter-nasal and the rostral; rostral equilaterally triangular; supra-nasal broad, heptangular, with apex to the front; fronti-nasals subtriangular, a little elongated; frontal obtusely subtriangular; parietal inequilaterally pentangular, with obtuse posterior base, single and as large as the frontal. A large subquadrilateral plate under the eye, and three small transversely narrow plates in front of it, and posterior to the nasal plate. A large diamond plate on centre of chin, emarginated anteriorly to admit a small roundish plate which is bordered by the anterior laterals. The tail shorter than the body, and sub-cylindrical, flattened below.

(2623) *SPHENOCEPHALUS TRIDACTYLUS*, Blyth, *n. s.* Very pale brown, a little deeper on the upper-parts. The largest of six specimens, measures 6 in. in total length, of which the tail is 2 in., and distance apart of the fore and hind limbs  $\frac{1}{2}$  in. Length of fore-limb  $\frac{1}{8}$  in., of hind  $\frac{1}{4}$  in. From Afghanistan, Presented by Dr. Allan Webb.

The habit of this curious reptile is indicated by its structure. It is evidently a burrower, probably into loose sandy soil, where it would work its way with its wedge like muzzle, deriving considerable *appui* from its hind-limbs; the minute fore-legs remaining generally close within the grooves into which they fit; the head meanwhile being raised, and the long body arched,—an attitude which most of the specimens assumed when immersed in spirit.

The following is a remarkable limbless lizard from Rangoon, obtained by purchase.

(2624) *OPHISEPS*, Blyth, *n. g.* Form anguine, of nearly uniform bulk throughout, tapering suddenly at the extremity of the tail; no exterior trace of limbs; and the vent placed in the middle of the entire length; the body above, and tail above and below, covered with parallel ranges of quadrilateral keeled scales, the throat and belly with hexagonal smooth scales, and the tapering extremity of the tail with imbricated and rounded scales. A groove on each side from shoulder to vent. Tongue obtusely forked: no palatal teeth; but a single row of small maxillary teeth: the triangular incision of the palate large. Eyes rather small, lacertine; the lids scaly. Tympanum small. Nostrils small, lateral. Head conical, somewhat compressed in front; the cleft of the mouth extending

to beyond the eye. Rostral plate small, broad, triangular; it and the nasals and anterior labials surmounted by numerous small plates and larger representatives respectively of a posterior nasal and united fronti-nasals. Frontal shield large, heptagonal with posterior base; and the parietal inequilaterally pentangular, with anterior base. Fronti-parietals quadrangular. The streaks of the chin are sub-quadrangular and placed obliquely. Along the median ridge of the back the parallel ranges of scales alternate, but not upon the tail.

(2625) *OPHICEPS TESSELLATUS* Blyth, *n. s.* Length of specimen  $12\frac{1}{2}$  in., of which the tail measures  $6\frac{1}{2}$  in. Colour pale dingy buff-yellow, paler below, with numerous plumbeous spots on the anterior half of the body above, composed of scales of that colour, some detached, others placed contiguously to form transverse bands more or less imperfect; all the scales being highly lustrous. There are 14 parallel ranges of them above from lateral groove to groove, and 8 such ranges below. From Rangoon.

*Notices and Descriptions of various Reptiles, new or little known.*—BY EDWARD BLYTH.—(Continued from Vol. XXII. p. 655.) No III of 1854.

(2626) *CALAMARIA CATENATA*, Blyth, *n. s.* (*C. monticola*? Cantor, *P. Z. S.* 1839. p. 50). [Note. "*C. olivaceo fusca, colari, laete flavo, linea dorsali albicante, abdomine citrino. scut. abd. 125; scutel. subcaud. 44. Hab. Naga Hills.*"] No anterior frontals: the vertical plate broad, pentagonal, and almost as large as the occipitals: 13 rows of scales: scutæ 187; scutellæ 41 pairs. Predominant colour dusky above, formed by minute black specks upon a pale ground-tint; below pale buff with an iridescent lustre, and marked with lateral series of square black spots chiefly upon alternate scutæ. Four black lines throughout above, the upper bordering a pale medial streak, which is simple upon the tail, but along the body forms a concatenation of elongated oval spots. An imperfect whitish buff collar, and similar marks before and behind the eye. Length of specimen 17 in. of which tail  $2\frac{1}{2}$  in. From Asám. Mr. Robinson. [Note. This and other species sent by Mr. Robinson, we much suspect are from the Khàsya hills, or other upland territory.] *Beng. As. Soc. Jour. No. III of 1854.*

(2627) *CALAMARIA RETICULATA*, Blyth, *n. s.* Vertical plate hexagonal, angulated to the front, and not half so large as the occipitals: supraorbital large and subtriangular. Thirteen rows of scales: scutæ 136, 138; scutellæ 27, 28 pairs. Colour shining dull black, brilliant and iridescent below: minute yellowish-white specks on the sides of the mouth, throat, and along the sides of the body. In spirit the edges of the scales are seen to be of a deep black, imparting a reti-

culated appearance. The larger of two specimens measures 12 in., of which tail  $2\frac{1}{2}$  in. From Asám. Mr. Robinson.

(2628) *CALAMARIA TENUICEPS*, Blyth, *n. s.* Colour iridescent black above, yellowish-white below. Nearly affined to *C. Longiceps*, Cantor, but the head anterior to the eyes much less elongated, and the posterior frontals consequently are about as broad as long: vertical plate elongate-hexangular, broadest anteriorly: head conical, narrow; the jaws of equal length. Thirteen rows of scales. Scutæ 138; scutellæ 37 pairs. Length of specimen 14 in., of which tail 2 in. From the vicinity of Darjiling. Capt. W. S. Sherwill.

The two following species of this genus are remarkable for having the posterior frontals united.

(2629) *CALAMARIA FUSCA*, Blyth, *n. s.* Of an iridescent dull black colour throughout, the ventrals slightly margined paler. Head small, narrow. Vertical plate pentangular with rounded anterior base, the posterior lateral angles so obtuse in some that the plate might then be described as triangular: occipitals very large, elongated. Thirteen rows of scales. Scutæ 155-7; scutellæ 30-34 pairs. Length 15 in., of which tail 2 in. Young obscurely striated with longitudinal rows of pale dots. From Darjiling. Capt. W. S. Sherwill.

(2630) *CALAMARIA OBSCURO-STRATA*, Blyth, *n. s.* Much affined to last: the muzzle less obtusely pointed, and the anterior frontals conspicuously smaller. Iridescent brown-black, the underparts particularly lustrous; obscurely streaked throughout with a pale band occupying the adjoining portions of the fourth and fifth rows of scales on each side, a narrow pale line also along the middle of each of the first three rows, and three similar narrow pale lines along the back, all alternating with dusky lines. Thirteen rows of scales. Scutæ 153-163; scutellæ 40 pairs. Length of the larger of two specimens  $11\frac{1}{4}$ , of which tail 2 in. From Rangoon.

The next has both the anterior and the posterior frontals, respectively, united or undivided.

(2631) *CALAMARIA BICOLOR*, Blyth, *n. s.* Dusky plumbeous above, buffy-white below, throughout; these colours gradually blending, and not abruptly demarcated as in *C. Tenuiceps*. Vertical plate pentangular, broader than long, or forming almost a triangle laterally truncated: rostral large and broad; the muzzle consequently obtuse; and the head broader and flatter than usual in this genus. Seventeen rows of scales. scutæ 20; scutellæ 75 pairs. Length of a specimen  $19\frac{1}{2}$  in., of which tail  $4\frac{1}{2}$  in. From Asam. Mr. Robinson.

(2632) *CORONELIA CALLICEPHALUS*, Gray. *Ann. M. N. H.*, Dec. 1853, p. 390. [Note

When the above description was taken, we had not seen that by Mr. Gray which is less detailed.] A beautiful species, with form and scutation of head as in the European *Coluber Esculapei* (as figured by Schlegel); but the eye somewhat smaller. Nineteen rows of scales; scutæ 201-211; scutellæ 56-65 pairs. Colour a light brown, paler below. Head with a median black line over the vertical and occipital scutæ, and another continued from each eye to the first of a series of about 18 semi-annuli, which in the young consist of large and broad white-edged black spots, reaching down to the abdominal scutæ; but in adults the black of the anterior of these spots disappears more or less completely, leaving only the pale-margined black edge, so that two narrow black transverse bands remain in place of the single broad black spot of the young: also at about the ninth or tenth of the latter from the head, two narrow black dorsal lines commence, which at first are broken and irregular, but gradually become continuous and well defined towards and upon the tail, where they cross its transverse bands and are continued to the extreme tip. Length of a specimen 27 in., of which tail 4 in. From Asàm. Mr. Robinson.

(2633) *XENODON PURPURASCENS*, Schlegel. The varieties of colouring of this snake are extraordinary; even more so than those of *Lycodon Aulicus*. Two adults in spirit from Goalpara are entirely of a pale colour (evidently, however, much blanched), *without traces of markings*. Another, from Asàm, is of a dull red brown above, with narrow black transverse band; lower-parts reddish pearly, with two rows of somewhat indistinct black spots, mostly on alternate scutæ: head-markings indistinct. A third variety (*Coronella albocincta*, Cantor, P. Z. S. 1839, p. 50), also from Asàm, is of a clay colour, the scales black margined and sprinkled over with minute black spots, and the entire length marked with above 24 black-edged white semi-annuli; beneath, the black spots are more developed than in the last variety, and are more or less continuous towards the vent: the usual head-markings distinct. Two others, from Goalpara and Lower Asàm, nearly resemble the last, but have no white semi-annuli, nor markings underneath the tail or anterior third of body. Others, again, from various parts, including central [Note. Ammerkàntak, towards source of Nerbudda; 3700 feet elevation.] and S. India and Ceylon, also the Tenasserim provinces, have the upper-parts more or less dark, and variously freckled, often with imperfect semi-annuli placed near together, and alternately distinct and comparatively obscure: the underparts commonly spotless; and sometimes the collar quite black. A single young specimen from Ceylon has 3 rows of black spots continued upon each scuta as far as the vent, where the medial row ceases, and the other two rows are

continued to the tip of the tail: above, the black semi-annuli are divided, and the halves placed alternately to the right and left, becoming gradually indistinct upon the hinder half. Upon a first view, this might be considered a distinct species; but we can perceive no structural variation from the rest, and intermediate varieties most probably occur. In all, save the first, the peculiar markings of the head readily indicate the species; as do the rostral and anterior frontal plates from other Indian serpents.

(2634) *COLUBER NIGROMARGINATUS*, Blyth n. s. Nearly affined to *C. Radiatus*, Schlegel, but attaining the size of *C. Mucosus*, L., (*V. Blumenbachii*, Merrem): our largest specimen measuring  $7\frac{3}{4}$  ft. long of which the tail is 2 ft. 1 in. Colour a bright pea-green (changing in spirit to blue), paler below, each scale of the upper parts margined with black. Upon the shields of the crown the black margins are extremely slight though present, and they gradually increase in breadth posteriorly until about the middle of the entire length, when the two colours resolve into four black, alternating with three narrower blue, streaks which are continued to the end of the tail. Eye larger than in *C. Mucosus*, much larger than in *C. Radiatus*. One large superior and one small inferior præ-ocular plate; and a single frænal, the latter as in *C. Radiatus*, to which the present species bears a near approximation in the details of its structure. Sixteen rows of scales, the four median slightly carinated. Scutæ 192-4; scutellæ 116-132 pairs. Hab. Vicinity of Darjiling, where procured by Capt. W. S. Sherwill, who sent with it examples of *C. Radiatus*, *C. Korros*, and *C. Fasciolatus*. Dr. Kelaart has also favoured us with *C. Korros* from Ceylon; but the species does not appear to have been hitherto observed in the Indian peninsula.

(2635) *COLUBER PRASINUS*, Blyth, n. s. Wholly green, becoming verditer in spirit; glaucous below and bordering the mouth: 19 rows of slightly carinated scales; scutæ 205, 6; scutellæ 107, 8 pairs. Vertical shield triangular with rounded apex; rather larger than the supraorbitals, and rather smaller than the occipitals: a single large præorbital, and one elongate-oval frænal. Tail suddenly tapering. The larger of two specimens measures 37 in., of which tail 9 in. From Asàm. Mr. Robinson.

(2636) *COLUBER HEXAGONOTUS* (?) Cantor, [Note. J. A. S. XVI, 921.] var., adult. Length 4 ft., of which tail  $15\frac{1}{2}$  in.; the latter remarkably slender. Colour brown, paler below; the anterior fourth of the body marked with transverse dusky bands, which become gradually more obscure till they disappear. Seventeen rows of slightly imbricated scales, the median row hexagonal. Vertical plate large, pentagonal, broad to the front. Two præ-orbitals, the lower small

and bordered by the third and fourth labials; the fourth labial bordering the eye, which is of moderate size; two post-orbitals, and a third or infra-orbital bordering on the fourth, fifth, and sixth labials: nasals large, elongate, the nostril opening in the middle, near the outer border of the anterior frontal; a single small subtriangular frænal. Scutæ 195; scutellæ 144 pairs. Hab. Arakan (Ramei)?

(2637) *COLUBER DIADEMA*, Schlegel; *C. Opellii* Wagler. This is a little known species; and two examples of it in our museum (origin uncertain) would not be readily recognised from Russell's plate (11, 30) which would appear to have been taken from an old and remarkably thick individual. One of the Society's specimens is of about equal length to that figured by Russell, but is much more slender; the other is smaller. The markings of the head are very peculiar, as the transverse black band from eye to eye and continued below the eye, and the four black specks on the two occipital plates. Upon the nape is a longitudinal black stripe, followed by a series of black spots along the spine, the first few of them being round, the rest gradually assuming the appearance of short transverse bands, much more regular and placed nearer together than as represented by Russell: towards the tail they diminish in size, and upon it are reduced to a series of minute black specks. Their number, from head to base of tail, amounts to 75. Alternating with the dorsal bands is, on each side, a series of smaller lateral transverse bands, which begin on the sides of the neck as large round black spots, following two oblique streaks behind the eye, and disappear altogether on the tail. They are placed with great regularity; and on the borders of the abdominal scutæ is a further series of black spots, such are the markings of our larger specimen, these being of an unmixed black. In our smaller example, all the dorsal black bands have the middle of each scale marked with the pale clay-colour which constitutes the general ground-tint, the lateral streaks are less decided, but the spots on the borders of the scutæ are more so, and every alternate scuta has an additional spot near each lateral margin. There are 19 rows of perfectly smooth (or not carinated) imbricated scales. Eye rather large: a great upper and small lower præ-orbital; one large subquadrate frænal; two post-orbitals: and the fifth and sixth labials border the eye below. Scutæ 207-8; scutellæ 98 pairs. Length of our larger specimen 36½ in., of which tail 9¼ in.

(2638) *COLUBER PICTUS*, Daudin; *C. Plinii*, Merrem, (Russell, 1, 29). Of this little known species, Mr. Jerdon has favoured us with a young example, from S. India. It is a true Coluber, and not a variety of *Coronella Baliodeira*, Schlegel, as suspected by Dr. Cantor. [Note. J. A. S. XVI, 915.]

(2639) *HERPETODRYAS HELENA*, (Daudin). In the Society's museum are two specimens of a snake, from Darjiling and Rungpore respectively, which may represent a variety of this species. Colour nearly uniform brown above, yellowish-white below with two lateral rows of dusky specks, one speck on each side of every abdominal scuta; a slight dusky streak from behind the eye; a trace of a black V-like mark on the nape; and very obscure indications of body-markings analogous to those of Russell's figure (1, 32). Seventeen rows of carinated scales. The larger of two individuals measures 29½ in., of which the tail occupies 8 in., and head 1 in., Scutæ 139, 199; Scutellæ 84, 90.

(2640) *PSAMMOPHIS CONDANARIUS*, Gray (Russell, 1, pl. 27; very bad). Seventeen rows of smooth scales, of which the first row on each side is very broad, the second row less broad, and the rest narrow and lanceolate. General colour bright green above, pale yellow or yellowish white below: longitudinally striped, except more or less towards the head, with four pale bands: the upper occupying the fourth and half respectively of the third and fifth rows of scales, and bounded above and below with a more or less defined narrow black lines; the lower occupying the lateral margins of the abdominal scutæ and subcaudal scutellæ, and defined above and below with narrow black lines which are very distinct. A pale superciliary streak bordered with black commences from the nostrils, and another below the eye, occupying the upper half of the labials. Some also shew an ill-defined pale dorsal streak. Hab. Lower Bengal?

(2641) *LEPTOPHIS RUBESCENS*; *Dipsas rubescens*, Gray, Hardwicke's *Ill. Ind. Zool.* This seems affined to *Dendrophis rhodopleuron*, Schlegel, from Amboyna. The nareal apertures are remarkably minute and abruptly pierced in the centre of the nasals. Vertical plate narrow. Neck slender. Body much compressed. General aspect of colour reddish-brown, powdered over throughout, excepting on the chin and throat, with minute specks. A row of black spots along the spine. A brown central occipital stripe, and similar lateral stripe from nostril to ear. Seventeen rows of smooth scales. Scutæ 198; scutellæ 120. From Mergui. Capt. Berdmore.

(2642) *LEPTOPHIS ORNATUS*, (Shaw), var. Marked very like young specimens of *Coronella Russellii*, excepting on the head. Colour olive-brown, the upper-parts marked throughout with a regular series of transverse black bars, broader towards the head, narrower and becoming indistinct towards the end of the tail; these black bars set off by whitish edges. Head marked nearly as usual. From Ceylon, Dr. Kelaart.

(2643) *DIPSAS FERRUGINEA*. Cantor, P. Z.

S. 1839, p. 53. Head smooth and flat above, remarkably frog-like with somewhat pointed muzzle: anterior frontals very small; the supra-orbitals larger than the vertical plate. Canines above and below well developed. Tail suddenly tapering. Colour a dull somewhat ferruginous brown above, a little marked with black and white shewing between the scales; a broad dark lateral band throughout, and above it an obscure pale band: lower-parts buffy yellowish-white, with a narrow dark lateral band on each side, and the rest thickly sprinkled over with minute black specks. Head with a narrow black median line over the frontal and vertical plates, and another over the supra-orbital, meeting its opposite on the occipital and continued to the nape: black lines also border the lips and pass through the eye. Seventeen rows of scales: Scutæ 171, 175; scutellæ 56, 64 pairs. Length of one  $13\frac{1}{2}$  in., of which tail  $3\frac{1}{4}$  in. From Asam and the vicinity of Darjiling; Mr. Robinson and Capt. Sherwill.

(2644) *DIPSAS MONTICOLA*, Cantor, P. Z. S. 1839, p. 53. Affined to *D. Trigonota* in structure. Brown above, pearly-white below, separated by a broad black streak behind the eye: lower-most row of scales black-bordered for the anterior third of the body; and traces of other lines towards the head. Fifteen rows of scales: scutæ 158, 193; scutellæ 82, 106 pairs. Length of one 22 in., of which tail  $7\frac{1}{2}$  in. Hab. Asam; Mr. Robinson.

(2645) *DIPSAS NIGROMARGINATA*, Blyth, n. s. Also affined to *D. Trigonota*, with median row of dorsal scales broad and hexagonal. No elongated teeth. Colour throughout green above, the distensible skin black between the scales; yellowish-white below. Twenty-one ranges of scales: scutæ 252; scutellæ 182 pairs. Length of one 42 in., of which tail 11 in. Hab. Asam. Mr. Robinson.

(2646) *DIPSAS TRIGONOTA*, the most common species of India proper, attains to about 6 ft. in length, but is rarely met with so large and preys (at least those of medium size) chiefly on the *Calotes versicolor* in L. Bengal. Vertical shield as broad as in the Malayan *D. Multimaculata*, not less so as represented in Dr. Schlegel's plate. The markings are ill represented by Russell, who figures the young. The very young (about 9 in.) are of a pale ashy colour, with but slight traces of the markings of the adult; a faint lateral band consisting of three parallel somewhat darker lines is continued throughout the length, also a medial and two lateral abdominal lines, besides which the under parts are very minutely speckled. There is a white median frontal streak bordered with black, continued into a black occipital streak. When two or three feet long, the white frontal streak is retained and at the occiput are two diverging white lines, which converge and meet behind at the first of the series of imperfectly trian-

gular white spots bordered and set off with black, which are continued throughout the body; becoming gradually more ill defined towards and upon the tail. The lower-parts are now pearly-white, a trace only of the lateral abdominal lines appearing as a row of small spots on each side, though not regularly upon every scuta. The full grown adult is altogether much darker, with the white markings tending to become obsolete; a conspicuous median black stripe is continued over the forehead and occiput, and another proceeds backward from each eye. Abdomen more or less speckled, with the lines of lateral spots more or less apparent.

(2647) *TROPIDONOTUS ZEBRINUS*, Blyth, n. s. (*Tr. chrysargos*,) Schlegel, var. ?) Vertical plate twice as broad as the superciliary, and of same length. One præ-orbital and three post-orbitals. Upper parts (in spirit) deep plumbeous, obscurely spotted with black; the sides and under parts yellowish white, the former throughout banded with black, and each band having a whitish spot (probably yellow in the recent specimen) above it. Head plumbeous above, the labial plates with a triangular black spot at the point of junction of each of their above, and exhibiting thus two larger spots posterior and two smaller anterior to the eye. Two or three distinct black bands across the nape. Rows of scales 15; scutæ 137; scutellæ 96 pairs. Length of specimen (which is quite young)  $10\frac{3}{8}$  in., of which the tail measures  $8\frac{1}{2}$  in. From Mergui, Capt. Berdmore.

(2648) *TROPIDONOTUS ANGUSTICEPS*, Blyth, n. s. Head narrow, not broader than the neck, little depressed, the eye much larger than in *Tr. umbratus*, and vertical shield broad. Colour (in spirit) plumbeous above, uniformly spotted with black throughout; below white more or less variegated with black on the hinder half: head without markings but a V-like mark on the nape with apex-towards the occiput becoming obsolete in adults. One specimen has 4 præ-orbital and 5 post-orbital plates; but in general these number 2 or 3 and 4: and the same specimen is remarkable for having no dark markings above, but some indistinct pale spots, probably of a vivid colour on the recent snake. In an adult the black spots on the upper parts are almost confined to the skin between the scales, and there is no blackish colour on the hinder half underneath. Seventeen rows of scales: scutæ 167, 172; scutellæ 57, 67 pairs. Length of an adult 41 in., of which tail  $8\frac{1}{2}$  in. Inhabits Asam and Arakan.

(2649) *TROPIDONOTUS SUBMINIATUS* (?), Schlegel. A most variable species, affined in structure to the preceding. One 16 in. long has the upper-parts speckled over with black and bright yellow on a greenish ground, under-parts whitish throughout. Head plumbeous above: a large black patch behind the eye,

occiput, surrounded except in front by orange-yellow border, behind which again the nape is bright vermillion, chiefly between the scales. A conspicuous black streak below the eye, and two black spots posteriorly towards the gape: scutæ 147; scutellæ 94 pairs. Another, rather larger, has the back almost plain dark plumbeous, paler and spotted with black towards the nape; lower-parts freckled with minute black specks, and increasingly so to the tail tip: occiput and nape green, crossed with two orange bands, becoming redder posteriorly. All the upper labials with a black strip, where each adjoins the next. Scutæ 157; scutella 66 pairs. A third, 29 in. long, has the upper-parts dark olive brown, with bright yellow spots on the skin between the scales; the lower dull pearly: nape green, followed by a vermillion space: a single broad black streak below the eye. Scutæ 155; scutellæ 83 pairs. The above three specimens are from Asam. Numerous others from Rungpore and Arakan, are mostly similar to the last, with generally a double black streak below the eye uniting beneath, rarely a single streak, and one large specimen has no streak below the eye: this would seem to disappear with age. Rows of scales 17, 19: scutæ 150, 166; scutellæ 60 to 90 pairs, but generally intermediate. Tail in all suddenly tapering. Largest specimen, which is much thicker than the others (denoting maturity), 3 ft., of which tail  $8\frac{1}{2}$  in.

(2650) *TROPIDONOTUS MACROPS*, Blyth, n. s. Eye very large; the vertical shield broad, and posterior frontals twice as large as the anterior. Prevailing hue of the upper-parts a dull vinaceous, many of the scales margined with black, and some with yellow: a series of yellow spots (about 50 in number) continued along the spine to the extremity of the tail, with a row of black spots on either side. Head and neck plumbeous, diverging on the nape where the first of the series of yellow spots is placed; a slight whitish V-like mark on occiput. Lower parts yellowish-white, with specks and powdering of dusky; more prevalent towards and upon the tail. Seventeen ranges of scales: scutæ 164-6; scutellæ 130-46 pairs. Length of largest specimen 31 in., of which tail  $6\frac{1}{2}$  in.

Two specimens closely resemble, but a third presents some differences of colour. The row of yellow spots is wanting along the spine, also the dark band on the nape, and the pale V-like occipital mark: the under-parts also are more uniformly whitish: scutæ 168; scutella 124 pairs only. All are from near Darjiling. Capt. W. S. Sherwill.

(2651) *TROPIDONOTUS DIPSAS*, Blyth, n. s. Form as in *Dipsas*, slender, the neck much compressed. Head oval, flattened above; eyes large; the muzzle anterior to the orbits short: nostrils small, opening quite laterally;

the nasal and rostral shields being vertical. General colour plumbeous above, obscurely spotted with black, and two barely traceable lines of whitish spots, more distinct towards and upon the neck where they increase in size towards the head. Occiput black, with an elongated white medial spot, and white V-like mark behind it, the apex of which is prolonged a little backwards. A narrow black line from eye to eye passing in front towards the muzzle; and broader black streak posterior to the eye, continued as a series of longish oval spots on the sides of the neck bordering the scutæ. Some black marks also on upper labials. Under-parts white throughout, with a row of minute black specks on either side. Rows of scales 17: scutæ 160;—scutellæ 90 pairs. Specimen (young)  $21\frac{1}{2}$  in. long, of which tail  $4\frac{1}{2}$  in. Vicinity of Darjiling. Capt. W. S. Sherwill.

(2652) *TROPIDONOTUS PLATYCEPS*, Blyth, n. s. A beautiful species, with small and flat (but not broad) head, having much the aspect of a *Herpetodryas*. [Note. Perhaps *H. FRÆNATUS*, Gray, (Ann. M. N. H. December 1853, p. 390,) may prove to be a variety. Young specimens generally shew the two white dots on the occipital shields, seen also in *Tr. umbratus*. Frontal and nasal shields vertical. Head and upper-parts deep green with slightly, black-edged scales; the lower-parts bright yellow with a coral red stripe bordering the abdominal scutæ on each side, and strongly tinging the sides of the body: subcaudal scutellæ variegated with greenish-dusky, and traces of the same about the throat. A white streak bordered with black passes backward from behind the eye and then upward to the occiput, but this would seem to disappear with age. Such is (or was) the colouring of two specimens respectively 27 in. long (of which tail 8 in.), and  $21\frac{1}{2}$  in. (of which tail  $6\frac{1}{2}$  in.) But another,  $21\frac{1}{2}$  in. long, is remarkable for having the chin and throat quite black, also the black markings of the dorsal scales more strongly developed than in the others, and the black marblings of the subcaudal scutellæ are more intense: the lateral coral-red band is merely indicated; and the white streak behind the eye is more strongly developed and continued forward to the muzzle. Number of rows of scales 19: scutæ 174, 86; scutellæ 89, 99 pairs. Another, from Asam, appears identical, but has 155 scutæ only; and in spirit appears of a dull olive-green colour, with two longitudinal pale ruddy dorsal stripes, much as in *Tr. stolatus*, and the lower parts are marked throughout with a black lateral spot on each scuta, seen also in the black-throated specimen. A small young example from the Khasya hills is similar to that from Asam. The three first described are from near Darjiling. Capt. W. S. Sherwill.

(2653) *ELAPS PERSONATUS*, Blyth, n. s. Vertical

## NEW OR LITTLE KNOWN.

plate about equal to the posterior frontals : supra-orbitals large, subquadrangular, elongate. Colour of upper-parts bright red in the adult, brown or reddish-brown in the young : marked throughout with from 22 to 28 narrow black semi-annuli having light whitish margins : under parts dull yellowish-white, mottled throughout with black patches more or less developed : head black above, with whitish muzzle and broad cross band posterior to the eyes. Scales lustrous ; 13 rows above : scutæ 196, 218 ; scutellæ 29, 34 pairs. Length of largest specimen  $24\frac{1}{4}$  in., of which tail  $2\frac{1}{4}$  in. From Asam.

(2654) *RANA ROBUSTA*, Blyth *n. s.* A moderately large Frog from Ceylon. Limbs exceedingly thick and massive ; the third-digits fully webbed. Skin subgranulose, especially on the lower parts. A slight transverse fold on the breast. Colour dusky above with a large black patch on the back, another on the croup, and smaller lateral patches. Lower-parts yellowish-white, with a V-like mark on the lower surface of the thigh in one of two specimens, both males. The same individual has dusky spots or imperfect streaks on the lower surface of the thigh, and its posterior surface is marked with longitudinal streaks of alternating black and yellowish-white. Digital membrane speckled with black. Length from snout to vent 3 inch, and of hind-limb 4 in., of which the foot is half. Presented by Dr. E. F. Kelaart.

(2655) *LYMNODYTES MACULARIUS*, Blyth, *n. s.* Differs from *L. erythræus* by the slightly but distinctly papillose skin of the back, and non-verrucose posterior surface of thighs ; by its shorter and stouter limbs, and short anterior digits, the two outermost of which have their terminal disks smaller than in *L. erythræus*. There is a broad black band from nostril to loin, bordered above and below by narrow pale yellow streaks. Entire lower-parts spotless light yellow, as also the upper lip. A black spot at the shoulder, and line along the posterior surface of the fore-limb. One or more similar lines on the hind-limbs ; the thighs beautifully mottled with black ; and a black medial line along the back, which becomes double over the loins. Length of male from muzzle to vent  $2\frac{3}{8}$  in. ; of hind-limb  $3\frac{3}{4}$  in. ; of which the foot measures  $1\frac{3}{4}$  in. Hab. Ceylon. Dr. E. F. Kelaart.

(2656) *LIMNODYTES LIVIDUS*, Blyth, *n. s.* A large species with short and remarkably fleshy thighs. Colour dusky above, paler and tinged with ruddy on the sides which are spotted with black. Chin, throat and breast, minutely variegated pale and dusky. Belly and thighs underneath, sullied whitish. Above, the thighs and shanks are paler than the back and tinged with ruddy, having several dusky cross-bands. Posterior surface of thigh smooth or non-verrucose. Length from muzzle to vent  $3\frac{1}{4}$  in., and of hind-leg  $4\frac{1}{2}$  in., of which the foot is  $2\frac{1}{4}$  in. From Colombo, Dr. E. F. Kelaart.

(2657) *MEGALOPHRYS GIGAS*, Blyth, *n. s.* (Edible Frog of Sikim, vide J. A. S. XXII, 557.) Adult male  $4\frac{1}{2}$  in. from snout to vent ; hind-foot  $7\frac{1}{2}$  in., of which foot from heel  $3\frac{3}{8}$  in. Breadth of head 2 in. Interdigital membrane of the hind-foot well developed. Fore-limbs extremely thick, with the skin of their inner surface highly granulose. Upper-parts uniformly dull reddish or purplish black, a little marked with white on the posterior surface of the thigh : below whitish, much suffused with dusky, and some irregular white spots or marblings along the rami of the lower jaw, and also on the sides of the body and along the sides of the limbs. What appear to be the young have the head proportionally less broad than in the adult, and the upper-parts have more of an olive tinge, and the under-parts are ochreous-yellow, mottled with reddish-brown. Hab. Sikim Himalaya. Capt. W. S. Sherwill. [Note. Two other forms affined to *Megalophrys*, and like it and *Bombinator*, exhibiting no external tympana, also sent from the Sikim Himalaya by Capt. Sherwill, we have at present no means of classifying, for want of books of reference.]

(2658) *BOMBINATOR SIKIMMENSIS*, nobis, *n. s.* Size and general character of the European *B. Igneus*, (Laur.), but the hind-toes free or slightly webbed only at their extreme base. Male with four large subquadrilateral papillose callosities on the breast, and corresponding callosities on the upper surface of the innermost digits of each four-foot. The tubercles of the head, body, and limbs, much more developed in males than in females. On the back are four irregular rows of large porous tubercles, and numerous minute tubercles without pores stud the rest of the upper-parts. On the hind-limbs small porous tubercles are very regularly disposed. Colour dull livid olive-green above, a little banded of the limbs ; flame-coloured below, more or less marbled with dusky. Presented by Capt. W. S. Sherwill.

(2659) ADDENDA. Since the former part of the foregoing paper was published, the author has had an opportunity of shewing the Society's specimens of Burmese Tortoises to the Rev. J. Mason of Maulmein, who has long devoted considerable attention to the zoology of the Tenasserim provinces. This gentleman immediately recognised the *Testudo megalopus* (J. A. S. XXII, 640,) as the species with which he was most familiar in Burma : at once distinguishing it from the Indian *T. Stellata* : and as his judgment is worthy of confidence, we may pretty safely now rank *T. megalopus* as a third Burmese species of the genus.

At about the same date of publication, appeared a paper by Dr. Gray on some undescribed species of reptiles collected by Dr. Joseph Hooker in the Khásia mountains and Sikim Himalaya. Among them, his genus *Dopasia* approximates

Blyth's Ophiseps (J. A. S. XXII, 655), but is evidently distinct; the position of the vent in Dopasia is not stated. *Parias maculata*, Gray, is identical with *Trigonocephalus nilgiriensis*, Jerdon, J. A. S. XXII, 524, as we find upon comparison of a fine Asamese specimen with the descriptions by Messrs. Jerdon and Gray, and with a coloured figure sent by Mr. Jerdon. Mr. Gray does not give the number of rows of scales or of abdominal or caudal plates. Mr. Jerdon writes—"23 rows of carinated scales, scutæ 142; scutellæ 36." The Asamese specimen has 23 rows of the first; scutæ 143; scutellæ about 36 pairs. Length  $14\frac{1}{2}$  in., of which tail barely two in. Colour pale, variegated with dark blackish-edged patches on the upper parts, forming irregular transverse bands, more or less divided and the halves alternating; below whitish, the plates speckled laterally with dusky; chin and sides of throat blackish; a whitish band proceeding backwards from the eye, another from cleft of mouth, and between them a black space. This Asamese specimen has an elongated black occipital spot, succeeded by two lateral streaks which unite posteriorly; a somewhat different arrangement from that in Mr. Jerdon's drawing, and again different from that exhibited in an example from the vicinity of Darjiling, which also has the underparts much more mottled with black; but all are evidently identical in species.—*Bengal As. Soc. Jour.* No. III of 1854.

(2660) RHINOCEROS. According to Captain Smith, (*Five years in Nepaul*), the Rhinoceros uses its tusches like the boar, in attacking animals. These are the weapons it brings into deadly play and not the horn as may people believe. On one occasion he witnessed a Rhinoceros in Nepaul, destroy an elephant with its tusches. p. 90.

#### (2661) ROSE OF SHARON.

Go, Warrior, pluck the laurel bough,  
And bind it round thy reeking brow;  
Ye sons of pleasure, blithely twine,  
A chaplet of the purple vine;  
And Beauty, cull each blushing flower,  
That ever deck'd the sylvan bower;  
No wreath is bright, no garland fair,  
Unless sweet Sharon's Rose be there.

The laurel branch will droop and die,  
The vine its purple fruit deny,  
The wreath that smiling beauty twin'd  
Will leave no lingering bud behind;  
For beauty's wreath, and beauty's bloom,  
In vain would shun the withering tomb,  
Where nought is bright and nought is fair  
Unless sweet Sharon's Rose be there.

Bright blossom! of immortal bloom,  
Of fadeless hue, and sweet perfume:  
Far in the deserts' dreary waste,  
In lone, neglected beauty placed,

Let others seek the blushing bower,  
And cull the frail and fading flower,  
But I'll to dreariest wilds repair,  
If Sharon's deathless Rose be there.

When nature's hand, with cunning care,  
No more the opening bud shall rear,  
But hurled by heaven's avenging Sire  
Descends the earth's consuming fire,  
And desolation's hurrying blast  
O'er all the saddened scene hath past,  
There is a clime for ever fair,

And Sharon's Rose shall flourish there.—F.

(2662) ROXBURGH, Dr W. formerly Superintendent of the Botanical Garden at Calcutta. Author of the *Flora Indica*. Died early in this century.

(2663) ROYLE, Dr. J. F. A writer on the botany, the commercial products, the cotton and fibrous plants of India. A medical officer of the Bengal army; died in the beginning of 1858.

(2664) RUBY LOCALITIES. Fine rubies have, from time to time, been discovered in many of the corundum localities of Southern India, associated with this gem, particularly in the gneiss at Viralimodos and Sholasigamany. The natives inform that it occurs also in the Trichingode talook and at Mallapollaye, but it is rare, comparatively speaking.

#### (2665) ROTTLERIA TINCTORIA.

*Red powder.*

Room, HIND.	Renee, HIND.
Ralee, HIND.	Kumbhal, HIND.

Abounds in the Kherei jungle, Dehra Dhoon, and Kohistan of the Punjab. The red powder of its fruit, brushed off and sold under the above names in the bazars of the N. W. provinces, is much valued by natives as a vermifuge.

Among the Europeans serving in the Punjab, tape worm is very common. It is also prevalent among the Mussulman portion of the inhabitants. At Mean Meer, Dr. Gordon met with success in expelling the tape worm by a native remedy called Kamila. This remedy, the powder from the capsules of *Rottlera tinctoria*, though not of recent origin, seems to have been first extensively used by Dr. McKinnon, of the Horse Artillery, who published a brief account of it in the *Indian Annals of Medical Science* for October 1853, as an extract from the Superintending Surgeon's annual sanatory report for the Punjab division.

The Kamila has long been known to the natives, and used all over India as a dye; it is also occasionally administered by them as a vermifuge.

In the Patna *Materia Medica* under the name of Kapila (a misprint), its properties are considered as of a warm nature, and given internally as an anthelmintic.

In Dr. Royle's *Materia Medica*, it is mentioned as a native vermifuge, and Dr. Royle seems to think its action depends on the stellate hairs found in the powder.

Kamila is the powder brushed off the capsules

## ROTTLERIA TINCTORIA.

of the *Rottlera tinctoria*, Roxb. It is also found sparingly on the leaves, petioles, and flower stalks of the plant.

The *Rottlera tinctoria* is a species of euphorbiaceæ founded in the hilly portions of India, as along the base of the Himalayas from Assam to near Peshawur, in Central India, in the Northern circars, in Mysore, and at Parell Hill near Bombay. In its habit it is almost arborescent, growing to 20 or 30 feet high.

The genus was named by Roxburgh, after Dr. Rottler, a Danish Missionary, and one of the fathers of Indian Botany.

The powder is of a dark brick red colour, with a peculiar heavy odour, increased on its being rubbed between the fingers.

There are two varieties of it sold in the bazars in the Punjab, the difference consisting in the one having been passed through coarse cloth to free it from impurities, such as portions of the withered flowers, dust or insects.

The only appreciable difference is that this finer quality is cleaner than the other.

To cold water the powder does not impart its yellow colour, but either floats on the surface or falls in small quantities to the bottom. Boiling water becomes slightly tinged by it.

If Kamila is boiled in water to which any of the alkalies have been added, a complete solution of the colouring matter takes place, and it is by means of this property that the natives of India avail themselves of it as a dye. Alcohol and ether dissolve it with equal facility. All these preparations of Kamila have a dark red colour, and the yellow colouring matter is only separated on the addition of certain re-agents. Thus, when the mineral acids are added to the alkaline decoction or infusion, a thick flocculent precipitate of a gamboge yellow colour is thrown down, and the same effect is produced on the alcoholic and ethereal tinctures on the addition of water or the mineral acids. Contact with the atmosphere seems to cause the development of this yellow deposit, as on exposing on glass a thin film of either of the tinctures before evaporation of the fluid is completed, the previously transparent coating becomes opaque and of a light yellow colour.

The process of dyeing seems also to bear on this idea, as silk or cloth is merely dipped in a hot alkaline solution which I have above described as of a dark red colour, and on the drying of the cloth the characteristic yellow colour is developed.

This resinous deposit, on which the active properties of the plant both as an anthelmintic and a dye depend, are obtained in a large quantity from an alkaline decoction of the powder in the following manner. Boil 8 ounces of the powder in two pints of water, along with 1 ounce of the bicarbonate of soda.

This was filtered when cool, and to the filter-

## RUMINANTS.

ed liquid nitric acid was added till the solution became neutral. A considerable quantity of yellow matter then formed in the fluid, which was again filtered, and this yellow residue, when dry, was found to weigh one and half ounces.

It was of a dusky yellow colour, and adhered in lumps of considerable consistence.

The substance probably exists in the plant as an essential oil, and the formation of the yellow coloured deposit, on the neutralization of alkaline solutions and the addition of water or the acids to the alcoholic and ethereal solutions, or by the action of air, consists in the change of the essential oil to a resin, by the loss of hydrogen and the absorption of oxygen.—

In all parts of India the Kamila is extensively used as a dye, especially for silk, to which it imparts a fine yellow colour. It is also employed to dye cotton cloth.

The following is the process of dyeing as pursued in Umritsir, the second city of the Punjab, where a large trade in silk is carried on. Barilla, a coarse preparation of carbonate of potash, obtained by burning a herbaceous species of *salsola* common in the uncultivated portions of the Punjab, is mixed with water, in the proportion of one ounce of barilla to four ounces of water. To this solution, when filtered, the Kamila is added, and they are then boiled together. When the boiling has been continued long enough to extract all the colouring matter, a small quantity of lime is dissolved in the fluid.

The dye is then ready for use, with the exception of the addition of few grains of alum, in order to fix the colour. In some parts of India, I understand that gum is occasionally mixed with fluid, but in the Punjab this is never considered necessary. The characteristic yellow colour is not developed in silk, &c. until after two or three immersions in the dyeing fluid. As a remedial agent, Kamila is well known to the natives.

It is almost only as an anthelmintic that it is employed medicinally by them, though in some districts it is used as an application to cutaneous diseases, especially for itch and fevers.—*Ind. Ann. Medi. Scie.* p. 85.

(2666) RUMINANTS, VARIOUS GENERA OF, by Mr. B. H. Hodgson, *Beng. As. Soc. Journ.* No 181, July 1847, p. 1685.

### CERVIDÆ.

Mrigadi Haranadi. [Note. The Sanscrit postfix *adi*, meaning et cœtera is the probable etymon, and certain equivalent of the Latin *idæ* and *inæ*.]

Hoofs cloven. Postal plane of scull forming an obtuse angle with frontal. Horns solid, falling annually, proper to males only, (save Rein Deer) inserted, superiorly and proximately, below the frontal crest. Front teeth in the lower jaw 8. None above; canines normal and constant, found in both sexes, or in the males only. Mo-

## RUMINANTS.

ears  $\frac{1}{2}$ . Mufle normal and constant (save only in Rein Deer and Elk). Teats 4, normally and constantly. Eye-pits constant. Groin pits vaguely defined or wanting. Feet-pits usually present, in all 4 feet or only in the hind.

(2667) *Genus CERVUS*. Stags.

Mriga Haran.

Horns in males only much branched, 2 basal, one central, and several terminal, snags.

Mufle [Note. See N. B. at end for explanation of all these organs] large covering the front, of upper lip.

Eye-pits moderate and moderately mobile S. shaped.

Feet-pits large in all 4 ? feet.

Groin-pits none.

Calcic gland tuft posterior and external.

Teats four.

Canines in males only.

Types, *Cervus elaphus* of Europe 2 *Cervus affinis* of Saul forest or Mûl Bârah Sinha and 3 Geàna or *Cervus wallichii* of Tibet. These animals are further characterised by a very short tail, a large disc or pale space round the tail, and no proper mane. The Indian ones are confined to vast primitive forests on the plain.

(2668) *Genus RUCERVUS*.

Baraiya or Bârah Sinha.

Horns in males only, with one basal snag and no central one, but their summits many branched as in the true Stags or *Elaphus*.

Mufle large, covering front of upper lip.

Eye-pits moderate, mobile moderately.

Feet pits?

Groin-pits none.

Calcic gland and tuft?

Teats four.

Canines in males only.

Type, *Cervus elaphoides vel duvaucelli*.

This is the Baraiya or Bârah Sinha. It inhabits reedy marches and islands of great rivers along the whole Eastern and Northern skirt of Bengal and Hindostan. Never enters the mountains or forests. Herds enormous in the Islands of Brahmaputra. These animals are further distinguished like the true stags, by the absence of the heavy mane of the Rusas, and by a short tail which however has no true caudal disc and is longer than in the stags proper. ?

(2669) *Genus PROCERVUS*.

Gonr. or Gower and Ghòs.

Horns in males only, small, smooth, greatly divergent, and much bent in the beam, like Bos and furnished with only one ? snag which is basal and forward, another subterminal?

Eye-pits medial, vertical.

Feet pits none.

Groin pits none.

No calcic tuft nor gland?

Teats four.

## RUMINANTS.

Tushes in males only.

Type *Cervus dimorphe*. The Gonr. or Ghos.

Habitat Saul forest.

Further subordinate marks of this genus are:—

Tail short. No caudal disc. A mane.

The Gowers are not gregarious. They are confined to the Saul forest so far as appears. With their rutting season and gestation, unacquainted. Intestines 56 feet, small 29, great, 27, Cæcum, 19 inches by 4, diameter of small gut  $\frac{3}{4}$  inch. Liver 3-lobed and a lobulus. Lungs 4-lobed Gall-bladder.

(2670) *Genus RUSA*.

Samber, Jarai, (vulgo Jerrow.)

Horns in males only, trifurcate: 1 basal and 1 subterminal snag. No central one.

Mufle large, covering the front of upper lip.

Eye-pits very large and completely reversible.

Feet-pits large in all 4 feet.

Groin-pits none.

Calcic gland and tuft, posterior and external.

Teats four.

Canines in both sexes.

Type, *Hippelaphus* or the Sambur, and *Aristotelis* or the Jarai: both continental species of India.

Also, in the Islands, *Equinus Peronii*, Etam, and *Marriannus*: but they want testing all of them.

Habitat, all the great forests of India and of its islands, and to a certain extent, the mountains above them, where the other large Deer are never seen.

These animals are not gregarious: they have a long bluff tail like that of a docked horse, no disc round it; but a heavy mane over the whole neck.

One anomalous species thence called *Heterocerus* has no upper snag to its horns. [Note Another large Deer of the Indo-chinese ranges of Hills is *Panolia Eedii*, the *Cervus frontalis* of Mr. McClelland. Not found West of the Brahmaputra.] The Rusas rut in spring and then drop their horns.

Their females gestate 3 months and produce young in winter, occasionally so early as the end of October, and one at a birth. In confinement the horns are usually dropt in April and take six months for their perfect replacement. The horns are not complete in form till the 4th year nor in size till the 8th year. Small gut 52 feet. Large 31. Cæcum 15 inches by  $4\frac{1}{4}$ .

(2671) *Genus AXIS*

Chittal. Chittra-chittri.

Horns in males only, with one basal and one subterminal snag as in *Rusa*, but the beam more bent and the horns paler and smoother, and closer grained in structure.

Mufle large, covering front of upper lip.

Eye-pits large, very mobile.

Feet-pits large in hind feet only.

## RUMINANTS.

Groin gland large; sinus vague.

Calcic gland and tuft, postcal and external.

Teats four.

Canines in males only.

Types, 1, *Axis major vel maculatus vel nudipalpebra*, or common spotted Deer or Chittal; 2, *Axis medius* or lesser spotted Deer or Jhow Laghuna; 3, *Axis porcinus vel niger*, or Hog Deer, or Para or Khae Laghuna, or Sugoria.

Habitat, general over the plains of India whence the progress of cultivation has long since driven the larger Deer or Barah Sinhas and Pusas and Gowers recte Gaur. These animals have a smooth, generally spotted, coat, no mane, and a long tail reaching to the back and ending in a point. It is singular that H. Smith should question their having eye-pits and canine teeth.

The spotted Deer are gregarious, the herds being often very large: the Hog Deer are less so, dwelling more in families. Their breeding season is May, June: their rutting season December, January. They gestate 6 months. Intestines of lesser spotted species  $65\frac{1}{2}$  feet, whereof the small are 40 and the great  $25\frac{1}{2}$ . Cæcum  $9\frac{1}{2}$  inches by  $3\frac{3}{4}$ , and 5 inches of gut below it, of same calibre; rest equal and narrow. Intestines of Hog Deer  $41\frac{1}{2}$  feet whereof the lesser are  $24\frac{1}{2}$  and the larger  $16\frac{3}{4}$ . Cæcum  $8\frac{1}{2}$  inches by  $2\frac{3}{4}$ . They rut and breed like the spotted species.

(2672) *Genus STYLOCERUS*, or Stilthorn or Muntjac.

Dària-Mriga; Ratwa, Kaker.

Horns in males only, small, raised on high hairy pedicles, and having only one snag which is basal.

Females with bristly tufts ending in knobs instead of horns.

Eye-pits very large and extremely mobile. Facial creases, large, mobile, glandular, placed along inner side of horn pedicles towards their very forward salient bases.

Feet-pits large, in hind feet only.

No groin-pits.

Mammæ four.

Canines in males only? large, trenchant, and exerted, as in the Musks.

No calcic gland nor tuft.

Types 1 sp. *Vaginalis* or the Kijang of Indian Islands.

2 sp. Ratwa or the Kaker of Indian Continent.

Habitat, general in India mountains and in forests at their bases. Never elsewhere. Seldom seen above 7000 feet in the Sub-Himalayas.

The Muntjacs are not gregarious though 6 or 8 are occasionally found together. They prefer the dells to the tops and the close to the open cover. Copse or brush wood of the Chinese bambu is a favorite retreat. They bark all the year but particularly in winter when the males are wanton. January, February is the common

## RUMINANTS.

rutting, and June, July the common breeding season: the gestation being 6 months, but they breed occasionally at any season though only once a year, and have one or two young at a birth.

The males horns fall in May and are perfect again in August. Intestines male 61 feet, whereof the small are 44 and large 17 feet. Cæcum 15 inches by  $2\frac{1}{4}$  inch and 9 inches of gut below it of same size. Rest,  $\frac{1}{2}$  to  $6\frac{3}{4}$  inch wide. Intestines female, 14 feet, whereof small 34 feet and great 15. Cæcum 12 inches by two, 12 inches of gut below it of like diameter.

### MOSCHIDÆ: THE MUSKS.

Kasturadi Mushkadi. [Note. See note in p. 688]

Feet cloven: no horns front teeth and below, none above. Molar teeth  $\frac{9}{8}$   $\frac{5}{8}$ . Canines large: cranium cervine with the two planes gradually blended.

(2673) *Genus MOSCHUS*: kastura. Mushk Hirn.

Musle large, as in Deer.

No eye-pits.

No feet-pits.

Large caudal gland with lateral pores.

No inguinal pits.

Calcic tuft and gland external postcal.

Large preputial gland and sac secreting the substance called musk, proper to males only.

Teats four

False hoofs very large, acute, and touching the ground.

Canines in both sexes: of males, large and exerted; of females, small.

Types, 1, *Moschiferus*; 2, *Chrysogaster*; 3, *Lucogaster*. Inhabit the great snowy mountain barriers of high Asia from the Himalaya to the Altai, and from Beluttag to the Peling and Gajar. The Musks are confined to the snowy region and glassy precipices which they leap with a power and security far more than Caprine, though owing to the unequal length of their legs they can descend slopes only with difficulty and falling are caught. They cannot climb at all, as Goats do, and are solitary. They rut in winter and produce young in summer (May, June) gestating 100 days. In 6 weeks the young can shift for themselves and the mother drives them off. They can procreate ere they are a year old and live 10 to 15 years. One usually is produced at a birth in the cavities of the rocks. Intestines 33 to 36 feet, whereof the small are 23 to 24 and the great 10 to 12 feet. Cæcum simple 8 to 9 inches by 1; mean diameter of gut 1 inch. Gall bladder [Prof. Owen doubts this. I have tested it a dozen of times since Dr. Campbell and I made the first examination in Nepaul] constant. (See Journal No. 87 and 118 and *Gleanings*, No. 34)

(2674) *Genus MEMINNA*: Pisora, Pisé.

## RUMINANTS.

Mufle large  
No eye-pits.  
No feet-pits.  
No groin-pits.  
Calcic gland nude and external.  
No preputial bag.  
Four teats.  
False hoofs, ordinary, small.  
Canines not exerted, and confined to males.  
Type, *Memina Indica* Pisora and Pisai.  
Inhabits the forests of India in all parts, near to, but without the various ranges of Hills.

### CAVICORNIE MINORES.

Lesser hollow horned Ruminants or Flocks.  
Hoofs cloven. Occipital plane of skull forming a small or large angle with frontal plane. Horns hollow, sheathed persistent, with thin and dense or thick and porous cores. Mufle small, for the most part, or wanting. Front teeth 8 below. None above. Canines present or absent. Molars  $\frac{a}{8}$  or  $\frac{a}{9}$ . Teats 4 or 2. Eye, feet, and groin, pits, present or absent.

### ANTELOPIDÆ.

Antelope kind.

Sasinadi.

Occipital plane of skull forming an obtuse angle with the frontal plane. Core of the horns thin, consisting of dense bone often with a clear sinus at the base within. Horns seated on the superior surface, below the crest of the frontals, and apart at bases. Canines frequent. Mufle present or absent. Teats normally 4 or 2. Feet-pits in all 4 feet or only in the hind ones.

Eye-pits present or absent. Groin-pits present or absent.

N. B. These animals have also occasionally maxillary, intermaxillary and post orbital sinuses, the number and high development of these organs being one decided characteristic of the family.

### (2675) *Genus* TERACERUS.

Chousinha, Chouka.

Horns in males only four in number. Two inter-orbital; and two behind eyes, but below crest of forehead.

Mufle large, as in Deer.  
Eye-pits medial, linear, longitudinal.  
Feet-pits in hind limbs only or none.  
No inguinal pits.  
No calcic tuft or gland.  
Teats four? two?  
Canines in the males.

Types 1, Chekara; 2, Quadricornis; 3, Subquadricornutus; 4, Jodes; 5, Pacceroois. (See Calcutta Journal Natural History for May, 1847.)

Inhabit the forests of India generally. Avoid mountains and open plains. Not gregarious. Rutting season, summer. Breeding season, winter. Gestate 6 months, most young born in January, February. They are very shy, and when hunted ie close or go off far ahead bounding like the

## RUMINANTS

common antelope, and hence one of their names, from chouk, a leap.

### (2676) *Genus* ANTELOPE.

Antelopes Proper. Sasin

Horns in males only.

No mufle

Eye-pits, medial, very mobile linear, vertically oblique.

Feet-pits large in all 4? feet.

Inguinal pits, large and clearly defined.

Calcic tufts?

Mamma two.

Type, *Cervicapra*. Black Antelope. Barant and sasin.

Very gregarious on the open dry plains of India generally.

I have no notes of their intestines or of the breeding.

### (2677) *Genus* GAZELLA.

Ghazal.

Horns in both sexes.

No mufle.

Eye-pits distinct mobile.

Feet-pits very large in all 4 extremities.

Inguinal pits large and distinct.

Calcic tufts?

Mammæ two.

Type Dorcas. Foreign to India.

### (2678) *Genus* TRAGOPS.

Chikara, Kalsipi.

Horns in both sexes.

No mufle.

No eye-pits.

Feet-pits large in all 4 feet.

Inguinal pits distinct.

Calcic tufts postæal.

Mammæ two.

Type, *Antelope bennetti vel christii*, found generally amid ravines of dry plains of India, called Chikara and Kalsipi by natives; Ravine Deer by Europeans. Not gregarious.

These animals have the lyrate horns common to both sexes, the knee tufts, lines along the flanks and ovine hairy nose of the 'Gazelles': but they are wholly void of eye-pits. The dark lustre of their large eyes is as striking as in the 2 last groups. [Note. This is one of the marks by which the Antelopine family may be distinguished from the small pale-eyed Goats or Caprine family.] Gazelles differ from Antelopes in that their horns are lyrate, and that the females also carry them. The Tragops differ from both by the total absence of the sub-orbital sinuses, or eye-pits.

### (2679) *Genus* PANTHOLOPS.

Chiru.

Molar teeth  $\frac{3}{4}$ .

Horns in males only.

No mufle.

## RUMINANTS.

No eye-pits.

Feet-pits large in all 4 feet.

Inguinal sacs, purselike, large, pendent.

Calcic tufts?

Mammæ, two.

Large intermaxillary sacs like double nostrils.

Type, Antelope hodgsonii, Abel. The Chiru.

Habitat open plains of Tibet. Gregarious, rutting season, winter. Breeding season, the summer. Gestate 6 months. One young at a birth. They are very pugnacious and jealous, and in their contests often break off one of their long horns. Hence the rumour of Unicorns in Tibet. (See Gleanings and Journal Asiatic Society, Nos. 2. and 27.)

(2680) *Genus* PROCAPRA.

Goa and Ragoa.

Horns in males only.

No muffle.

No eye-pits.

Feet-pits small in all 4 feet.

Post cornual sinus, large.

No inguinal pores.

Calcic tufts postæal.

Mammæ two.

Type, P. picticaudata. Goa of Tibet.

Inhabits ravines on the open plains of Tibet in small herds or families. See Journal Asiatic Society, No. 173.

(2681) *Genus* KEMAS.

Goral.

Horns in both sexes.

Muffle medial.

No eye-pits.

Feet-pits medial in all 4 feet.

No groin-pits.

Calcic tufts?

Mammæ four.

Type, Antelope Goral. The Goral.

Habit the Sub Himalayas, as far towards the snows as the great forests extend, to which exclusively these animals adhere. Dwell in families 4-6 together. Breed amid crags and rocky recesses. Young mostly born in May, June: gestate 6 months. Rutting season January, February. Produce one young at a birth.

(2682) *Genus* NEMORHÆDUS. Vel Capricornis. [Note. Sumatrensis is Col. Smith's type and Mr. Ogilby says this is identical in structure with the Thar; Mr. O.'s type of capricornis. If so, Col. Smith's generic name will have the priority; if not, it will be the type of Nemorhedus and the Thar of Capricornis. Col. Smith's several species of Nemorhedus are as heterogenous as Mr. Ogilby's of Kemas.

Thar or Saraw.

Horns in both sexes.

Muffle medial.

Eye-pits round and furnished with a very large gland.

Feet-pits extremely large in all 4 feet.

## RUMINANTS.

Groin-pits none.

Calcic tufts none nor gland.

Mammæ four.

Type, Antelope thar. The Thar or Saraw.

Habit the Sub-Himalayas as far north as the great forests extend.

Also, Antelope Sumatrensis of the Islands of India.

The Gorals and Thars have the round black and ringed horns of Antelope, which otherwise they little resemble being short clambering mountain animals, but not, as supposed, affined to the Bovines. The Gorals differ from the Thars by wanting the very glandulous eye-pits of the latter, and both are sundered from the Hemitragæ by their large feet-pits, Antelopine horns, and absence of Caprine odour. The Thars are not gregarious at all. They rush with fearful precipitancy down the steep mountains they inhabit. Rutting season, February, March. Young (one) born in September, October. Gestate 8 months. Small gnt 65 feet. Great 32 feet. Cæcum 15 inches long by 3 wide, and simple. Gall-bladder constant. (See Journal No. 45 for September 1855.

CAPRIDÆ.

Goats and sheep.

Bakaradi.

Occipital plane of skull forming an acute angle with frontal plane. Cores of horns thick porous and cellular. Horns seated superiorly on the crest of the forehead and by their union covering the top of the head. Canines wanting. Teats normally but two, rarely 4. Muffle abnormal and almost invariably absent. Feet-pits in all four feet or only in the fore-feet, or none. Eye and groin pits present or absent.

(2683) *Genus* HEMITRAGUS.

Jharal vel Tehr.

A small muffle.

No eye-pits.

No feet-pits.

No inguinal pores.

Calcic tufts.

Four teats.

Strong caprine odour in males.

Types. 1, Capra Jemlaica. 2 Capra Jharal vel Quadrimammis. 3, Capra Waryatu, whose female is Hylocrius. Habitat the loftiest mountains of India: the Sub-Himalayas near the snows and the highest part of the Nilgiris. A very remarkable type tending to connect the keeled, compressed hollow-horned and odorous Goats with the Deer family which want these marks, but possess the muffle and 4 teats of the Hemitragæ, marks which the true Goats (and sheep) are void of.

The Jharal's retreats are among the most inaccessible bare crags of the Hemachal, close to the perpetual snows, beyond the forests. They feed in the open glades below such crags at early morning and evening, retiring in the day.

## RUMINANTS.

to their awful fastnesses. They are gregarious and the flocks often amount to 40 or 50 animals, but generally do not exceed 20 or 30. If alarmed when feeding they go off at speed with a noise like thunder, but anon halt to gaze on the intruder, whose shot sends them off again under the guidance of an old male whom they all follow blindly. The rutting season is the winter. The females gestate 6 months and produce usually but one young in the months of June, July. The habitat and manners of the wild sheep are very similar to those of the jharals, only the latter are still more dauntless and skilful climbers. If they can but touch a rough edge or crevice now and then they will run up nearly perpendicular precipices of many feet elevation and they will stand on a bit of rock not larger than one's palm looking confidently down over sheer space with not a shrub to break the awful absence of rest for the foot. In February 1842, a male jharal in possession of the Court of Nepal had intercourse with a female Axis, which in July produced a young hybrid of mixed appearance, but more like the mother than the father, and which lived and grew up a fine animal. I saw it last in October 1843. I note the circumstance as a strong corroboration of that affinity of the Hemitragas to the Deer (not Bovines, as Mr. Ogilby supposed) which is indicated by the 4 teats and moist muzzle of the former, notwithstanding that the Hemitragas in all other parts of their structure as well as in their rank odour and in their manners are such perfect goats. From the true goats however they differ, besides grand points noted, by the total absence of beard and of feet pores. Nor could I ever get any progeny from the goats by the jharal, [Note. They copulated freely and I was told would breed. Hence the erroneous statement in the Journal for September 1835, disproved by experiments.] though a male of the latter species had commerce with Goats of several breeds, repeatedly, during the 6 years he lived with me, quite tame and going abroad with the sheep and goats. Small intestines 53 feet. Large, 25-78 feet. Cæcum 1 foot long and  $2\frac{1}{4}$  inches wide. Small gut  $\frac{3}{4}$  inch in diameter; great gut  $2\frac{1}{2}$ . Cæcum simple, that is, not banded nor sacked.

(2684) *Genus* CAPRA.

Bakra. Goats.

Horns in both sexes.  
No muffle.  
Feet-pits in the forefeet only or none.  
No inguinal pores.  
Mammæ two,  
Odour intense in males.  
Calcic tufts none.

Type, *Capra ægagrus*. Habit Persia. Foreign to India, and not therefore subject to my examination, but the several tame races of Tibet and the sub Himalayas (Chandra, Chyann, Sinal) and

## RUMINANTS.

and also the common Goats of the plains (*Dugu* and *Jamnalaria*) are *all* typical. These animals are further distinguished by horns inserted very obliquely, not angular, compressed, and presenting a sharp beveled edge to the front, whereby they may be distinguished at once from all kinds of sheep and also from the Ibexes. They have likewise invariably a true beard common to both sexes, as have also the Ibexes, but the sheep never: and, lastly, the Goats have callosities on the chest and knees or knees only. Eminently bold, saucy and scindent. Gregarious. But in winter. Procreate in summer. Gestate under 5 months? Produce 3, 2 or 1 young at a birth. (See paper on tame Goats and Sheep of these regions. Sp. Mag., for June, 1847.)

(2685) *Genus* IBEX.

Skin. Kin.

Horns in both sexes.  
No muffle.  
No eye-pits?  
Feet-pits none?  
No inguinal pores?  
Mammæ two.  
Odour in Males?  
Calcic tufts?

Types. *Europea caucasica*. *Jaela Sakin Sibirica*. Habitat the loftiest mountains of Europe, Asia, and Africa. Found in the Himalaya close to the snows. These animals with the general manners, the odour and the beards of Goats, are distinguished invariably by angular horns presenting a distinct surface, instead of a mere edge, to the front, thereby differing from the Goats proper and approximating to the Sheep. The front of the horns is likewise remarkably nodose, and the horns are of great size and sickle-like curved. Their structural peculiarities want testing and will doubtless show deviation from the type of *Ægagrus*. Rut in autumn. Breed in spring. Gestate  $5\frac{1}{2}$  months. Produce 2 or 1 kids. Gregarious, bold, and scindent.

(2686) *Genus* OVIS.

Bhéra. Sheep.

Horns in both sexes.  
No muffle.  
Eye-pits large but immobile.  
Feet pits small but present in all four extremities.  
Inguinal glands distinct. Pores vaguely defined.  
Calcic tufts and glands none.  
Mammæ two.  
No odour in males.

Types, *Ovis Ammon* or the Argali of Siberia, and *Ovis Ammonoides* or the Argali of Tibet.

Habitat the snowy barriers of high Asia, *Ammon* being confined to the remoter, and *Ammonoides* to the nearer ranges. These animals are further distinguished as a group by angular, compressed, heavily wrinkled horns turned al-

## RUMINANTS.

most into a perfect circle, and their flat points directed forwards and outwards; by very short disced tails; and by the absence of beard. The wild Sheep proper, or Nyens of the Tibetans, never mix with the Nahoor. They are far more hardy, active and independent than any tame breeds of their kind, as may well be supposed from their terrific abode amid the snowy peaks of Hemachal. They are gregarious, feed in the glens, seek refuge on the tops, and leap and run with Deer-like power, though as climbers inferior to the Hemitragas, and as leapers to the Musks. They are often snowed up for days without perishing, unless their breathing holes should betray them to man, a more terrible foe, than the direct uncleanness of the seasons! They rut in winter, breed in early summer and gestate, it is said, 6 months, probably not above 160 days. The Nyens or Ban Bheras (that is, wild sheep) seldom or never cross the Hemachal, the Indian side of which range is the special habitat of the Nahoor, while to the North and West beyond Tibet, our animals are replaced by other species, so that Tibet may be considered as the special habitat of one species and the plateaux North of Tibet as far as the Altai as that of the other species, above cited as types of the true ovine form, and it may here be added, that the six sorts of tame sheep of Tibet and the Sub-Himalayas, all, without exception, exhibit the essential characters of that form.

\* (2687) *Genus PSEUDOIS*. [See Jour. No, 173.]  
Nahoor.

Horns in both sexes.

No muffle.

No eye-pits.

Feet-pits small in all four feet.

Inguinal glands distinct. Pores vague.

Calcic tufts none.

Mammæ two.

No odour in males.

Types, *Ovis Nahoor* and *Ovis Barhel*.

Habitat the Himalayas.

These animals are contradistinguished, besides the want of eye-pits, by rounded uncompressed smooth horns directed upwards and backwards with great divergency and their round points again bent inwards; by short deer like tails, but longer than in the last and undisced; and, lastly, by the absence of any thing like mane or beard. The Nahoor rut in winter, breed in summer and gestate  $5\frac{1}{2}$  months. Their manners, so far as known, resemble those of the Nyens; but the two never commingle nor approach each other, nor will the males, how long and completely soever they be tamed have sexual commerce with domestic sheep. Great gut 24 feet. Small gut 50 feet. Cæcum 17 inches, by  $2\frac{1}{2}$  wide. Large gut near it, of same diameter. Liver 2 lobed each subdivided and a lobulus. Ribs 13 pairs.

## RUMINANTS.

(2688) *Genus CAPROVIS*.

Moufflons.

Horns in the males only.

No muffle.

Eye-pits small but distinct.

No interdigital pits.

Inguinal gland? pore?

No calcic tuft?

Mammæ two.

No caprine odour

[Note. This is the only form not verified by myself, that I have meddled with, and I am indebted to the Prince of Canino for its characters.]

Further distinguished by horns bent into a half circle over the back, heavily wrinkled, angular and compressed, by deer-like tails, no beard nor mane nor caudal disc.

Type, *Ovis Musimon*. The Moufflon. Habitat Corsica, Sardinia.

N. B. The 'Muffle' is the naked moist skin round the end of the upper lip and nostrils seen in perfection in the ox. The eye-pits are slits or punctures on the cheek, just below the eye. They are round or linear and elongate: and, if the latter, are curved or straight and can be turned almost inside out, are partially or wholly immobile. The 'foot pits' are punctures in front of the pastern, in the cleft between the two bones. The 'groin-pits' are fissures in the groin more or less defined in outline, and furnished with glands which secrete a fragrant viscid substance very like the secretion of the other sinuses.

The 'calcic glands' are placed on the stifle, inside and outside, or only the one, and are often naked and tumid externally. There is a whorl or callous nude spot in many quadrupeds at its side.

The 'tail gland' of the Musks is very large and covers the whole tail nearly, and has a linear longitudinal pore on each side and an abundant secretion.

The 'preputial gland' of the Musks is analogous to that of the civets and screwtail (*Paradoxurus*, vulgo Malwa). It is placed on the prepuce, the penis opening in the midst of it. This organ is clearly subservient to sexual purposes, and so probably are several of the others, though the eye-pits have been variously referred to the facilitation of breathing and of smelling. The supposed end of the interdigital gland and pore or feet-pits, viz, the lubrication of the foot and preservation of the hoof in hot sandy deserts, is clearly erroneous, since the Thar has these organs of an enormous size in all 4 extremities, though it be the tenant of moist cool mountain forests. It is probable that the secretion from the foot pores enables these animals to find one

## RUMINANTS.

Another in those wildernesses of vast forest trees and dense undergrowth which constitute their range.

The shape of the orifice and of the gland, and the nature of the secretion from the latter as well as the periodical augmentation thereof, should be closely attended to—and that *generally*, or with reference to *all* these pits or sinuses. The distinctive form of the upper outline of the skull, and character of the core of the horns in the Antelopidae or Antelope kind, and in the Capridae or Goat and Sheep kind, and again in the Deer kind and Ox kind, sketches will best make understood; and I would suggest particular attention to this point as a key, as well to the mutual affinities as to the differential characters of all these groups. The Antelopes are thus clearly separated from the Goats and Sheep, and distributed into two groups of their own, one that of the typical genera which class with the Flocks; the other, that of the abnormal genera, which range with the Herds.—I meddle not with the last named group or Bovine Antelopes (Bosdorcidae): but in regard to all the others, inclusive of the Musks whose Cervine affinities are thus made palpable, examine well the sketches and note the signal and abrupt fall of the postcal plane of the skulls in the Caprine and Bovine Families, and its gentle slope in the Cervine and Antelopine Families. The Antelopine skull depicted is that of the Thar, and you may thus satisfy yourself at once that this type (as well as Kemas) which agrees [Note. The agreement is not close, so that Goral is osculant towards the Capridae. The characters of both were printed by me (Journal, September 1835) a year and quarter before Mr. Ogilby, December 1836, Zool Jour.] with Nemorhædus in this important point) is an Antelopine not Bovine type. In like manner that is by attending to the form of the skull and the consequent position of the condyles—you may obtain demonstration of the caprine affinities of Hemetrages; and, in fact, the whole genera of these perplexing families may thus be set in order.

I now proceed to the Bovines or Ox kind.

CAVICORNIE MAJORES, or Bovidæ or Herds.  
Gaudrisha.

Hoofs cloven. Occipital plane of skull forming a large angle with frontal plane. Horns hollow, persistent, sheathed with a thick cellular core springing laterally from the apex of the forehead. [Note. These marks of the family may be supposed exclusive to the subfamily: but I apprehend not, and that they will serve usefully to sunder the antelopes allied to Bos and those not so allied, or Antelopidae and Bos dorsiniæ.] Muffle large. Front teeth, above none. Below 8 canine none? Molars 6. Teats four. Dewlap present or wanting.

## RUMINANTS.

### BOVINÆ OR OX-KIND.

Gauadi.

Occipital plane of the skull forming a large angle with the frontal plane. Core of the horns massive and very porous or cellular. Horns in both sexes, inserted laterally on the apex of the frontal crest. Canines none. Muffle very large. Teats invariably 4. Dewlap, in most, normally. No eye-pits. No feet-pits. No groin-pits.

(2689) *Genus* BOS. OXEN.

Gau.

Cranium moderate, compressed, proportional or with excess in the cerebral or facial region. Frontals shorter than the face, flat, and not broader than long.

Occipital plane of the skull square, never arched along the ridge line nor indented by the temporal pits, smaller than the frontal plane and forming an acute angle therewith.

Condyles of great foramen and of lower jaw, elevated greatly, and the jaw much curved.

Horns attached to the highest line of the forehead, rounded, curved up or down or forward ascendantly.

Orbits not salient.

Thirteen pair of ribs.

No true dorsal ridge, but sometimes a fleshy hump.

Muffle very large and square.

Dewlap great.

Type Bos domesticus. Gau.

(2690) *Genus* GAVEUS.

Gavi or Gabi.

Cranium large, having the ample flat forehead as long as the face and broader than long, but not ridged nor curved along its crest.

Occipital plane equal to the frontal plane and moderately indented subcentrally by the temporal fosses, square, and forming an acute angle with the frontal plane.

Condyles of great foramen and of lower jaw low, and the jaw little bent.

Orbits not salient.

Horns attached to highest line of forehead, more or less depressed, and angular, and directed upwards and outwards with little curvature.

A true dorsal ridge but confined to the withers.

Muffle moderate.

Dewlap moderate.

Thirteen pairs of ribs.

Type. Bos frontalis vel Gayæus vel Sylhetanus. The Gavi or Gabi. Habitat trans Brahmaputram, the forests under the ranges extending from Assam to the sea. The Senbar vel Phain may probably be a second species: and Bos Sondaicus or the Benteng a 3rd and the insular species: but these want testing. The first is more than half redeemed from the wild state like the yak of Tibet. The others are entirely

## RUMINANTS.

wild. I possess no memoranda of the soft anatomy or intestines, nor of the breeding season and gestation.

(2691) *Genus BIBOS.*

Gaur or Gauri Gau.

Cranium large, massive, with the frontal and cerebral portions preponderant over the facial.

Frontals as long as the face, broader than long, concave and surmounted by a salient arched crest.

Occipital plane spheroidal, very large, larger than the frontal plane deeply indented centrally by the temporal pits, and forming an acute angle with the frontal plane.

Orbits salient.

Condyles of great foramen and of lower jaw low, and the latter straight.

Horns attached below crest of forehead, sub-depressed, sub-angular, and curving ascendantly.

Thirteen pairs of ribs.

Dorsal ridge co-extensive with the ribs and of great elevation.

Mufle small.

Dewlap small.

Type *Bos gaurus* vel *Cavifrons*. The Gaur or Gauri Gau. Caesar's wild Bull of Europe and Aristotle's of Persia, are two other species of *Bibos* or of *Gaveus*, which could we test them might be respectively called *classicus* vel *Cæsaris* et *Aristotelis*. The Gaurs inhabit the primitive forests of India generally, under the great ranges of mountains, such as the sub-Himalayas, the Vindhias, the Sathpuras, the Glats, Eastern and Western, and their links with the Vindhias, and with the Nilgiris. Beyond the Brahmaputra, *Bibos* is replaced by the last type, of which there would seem to be two species in the Indo-Chinese countries, one of them extending to Ceylon, if the Lanka wild Ox be not rather a *Bibos*; I suspect there will prove to be at least two species of *Bibos*, as of *Rusa*, inhabitants of India between the Cape (Comorin) and the sub-Himalayas or *B. Gaurus* and *B. Cavifrons*.

For the skeleton of the Gaur, I may refer the reader to the Asiatic Society's Journal, No. 114, and No. 69. Of the intestines I possess no memorandum. The period of gestation was in Nepaul always stated to me to exceed that of the common Ox: but Mr. Elliot, will not allow this. The Gaurs rut in winter and procreate in autumn, producing usually but one young at a birth. The herds are ordinarily rather numerous 20, 30, 40, and sometimes even double these numbers, being found together, but in the breeding season, not above 10 or 15 cows with a single mature vigorous bull, who jealously expels every young and old male from his Haram. The sub-Himalayan species entirely avoids the open Tarai on the one hand, and the hills on the other, adher-

## RUMINANTS.

ing to the most solitary parts of the Saul forest: close to and between the salient spurs of the hills where the periodical firing of the under growth of the forest never reaches. In the Deccan these animals are said to penetrate into the hills in the hot weather—very partially, I fancy, or else they must then lack cover on the plain, for they are not a mountain race at all. They feed early and late in the more open glades of the forest, posting sentinels the while and manifesting in their whole demeanour a degree of shyness unparalleled among the Bovines. They never venture, even in the rains, when there is abundance of most rank vegetation to cover their approaches, into the open Tarai to depredate on the crops, as the wild Buffaloes constantly do, nor do they ever associate, or have sexual commerce with the tame cattle, though immense numbers of the latter every spring are driven into their retreats to feed, and remain there in a half wild condition for three or four months when the wild Buffaloes frequently have sexual intercourse with the tame ones of their kind, of which likewise vast numbers are depastured there. Old males of the Gaur are often found solitarily wandering the forests they frequent, especially in winter: but these have probably been recently expelled the herds by their more vigorous juniors, and re-unite themselves with some herd after the season of love and contention has passed. It is exceedingly difficult to rear the Gauri Gau in confinement. Nor did I ever know a successful experiment, though the attempt has been, for 50 years past, constantly made by the Court of Nepal, which finds no difficulty in rearing wild Buffaloes and causing them to breed in confinement with the domestic species, which is thus greatly improved in size and qualities. I have remarked on the excessive shyness of the Gaurs; and it follows that, when approached, they will retreat so long as they can: but if compelled to stand and defend themselves, they do so with a courage and determination not to be surpassed. Their beef is unequalled for flavor and tenderness: but to the aborigines only it is illicit food, and not to all tribes of them, nor are any of them allowed to kill the Gaur in Hindu kingdoms. The Gaur stands from 6 to 6½ feet high at the shoulder, and is either of a ruddy brown, alias tan, or of a black colour, the forehead and limbs below the mid flexures being pale, and the forehead and knees tufted. Capt. Tickell a good observer, believes that there are two species of *Bibos* in the Chota Nagpore territories *alone*! Doubtless close investigation will reveal many new species in the Bovinæ.

(2692) *Genus BISON.*

Yak. Chouri Gau.

Cranium moderate, depressed, with the facial portion exceeding the frontal and cerebral parts.

## RUMINANTS.

Frontals broader than long, convex and forming an obtuse angle with the occipital plane.

Occipital plane smaller than the frontal plane, trigonal or semi circular, and ridged by the parietes.

Orbits salient.

Condyles of great foramen and of lower jaw low, and jaw straight. Horns attached below the curved or bent intercornal ridge, rounded and curving out of the horizontal line.

Ribs 14 or 15 pairs.

A true dorsal ridge, confined to the withers.

Muscle small.

Dewlap none.

Types Americanus et Pœphagus.

The latter is the Yak or Chouri Gau.

It inhabits all the loftiest plateaux of High Asia between the Altai and the Himalaya, the Belut Tag and the Peling mountains, and is found wild as well as tame. It cannot live on this side the Himalayas beyond the immediate vicinity of the snows, where the tribes of the Cachar or Juxta-nivean region of the sub-Himalayas rear large herds and cross-breed with the common Ox. The yak ruts in winter and produces young in autumn, after the usual period of Bovine gestation. Small intestines 197 feet. Large  $33\frac{1}{2}$  feet. Cœcum  $2\frac{1}{2}$  feet. Width of small gut  $1\frac{1}{2}$  inches; of great, 2 inches; of Cœcum 4 inches. Cœcum simple, that is not saccæd nor banded.

(2693) *Genus* BUBALUS.

Bhainsa. Arna.

Cranium large, elongate, compressed, exhibiting great excess in the facial over the frontal and cerebral portions. Frontals short, narrow-convex, forming an obtuse angle with the occipital plane.

Occipital plane larger than the frontals, spheroidal, moderately indented.

Condyles of the foramen and lower jaw low and the jaw little curved. Horns attached to the highest line of frontals, depressed, angular, and horizontal.

Thirteen pairs of ribs.

No true dorsal ridge nor hump.

Muscle very large and square.

Dewlap medial.

Types. Bubalus Buffelus, or the Bhainsa, and Bubalus Arna or the Arna. [Bornouensis and Brachycerus are to my mind no Buffaloes, and their united horns form a character at variance not only with the genus but the family. Hence I denominate them from this feature Syncerus. They are foreign to India, the land of the true Buffaloes.]

Habitat of the tame, universal; of the wild, also every place where adequate cover and swamp exist. The haunts of the Arna or wild Buffaloe are the margins rather than the interior primeval forests. They never ascend the mountains, and adhere, like Rhinoceroses, to the most swampy sites of the district they frequent. There is no

## RUMINANTS.

animal upon which ages of domestication have made so small an impression as upon the Buffaloe, the tame species being still most clearly referable to the wild ones at present frequenting all the great swampy jungles of India. But in those wildernesses as in the cow houses, a marked distinction may be observed between the long-horned and curve-horned Buffaloes, or the Macrocerus and Spirocerus of my catalogue—which whether they be separate species or merely varieties, I shall not venture to decide, but incline to regard them as species. The length of the horns of Macrocerus is sometimes truly enormous, or  $6\frac{1}{2}$  feet each.

There is such a pair in the British Museum, and another pair I saw in Tirhut. The Arna ruts in autumn and the females produce one or two young in summer after a gestation of 10 months. The herds are usually numerous and sometimes exceedingly so, though at the season of love the most lusty males lead off and appropriate several females with which they form small herds for the time. I have no memorandum of the intestines of the Arna. This noble species is, in the Saul forest and Tarai, a truly stupendous animal, as tall as the Gaur and longer considerably and of such power and vigour as by his charge frequently to prostrate a well sized elephant! The wild animals are fully a third larger than the largest tame breed, and measure from snout to vent  $10\frac{1}{2}$  feet, and six to six and half feet high at the shoulder. The wild Buffaloe is remarkable for the uniform shortness of its tail, which extends not lower than the hock; for the tufts which cover his forehead and knees, and, lastly, for the great size of his horns and the uniform high condition of the animal, so unlike the leanness and angularity of the domestic buffaloes' figure, even at its best.

I have now disposed of all the Bovines proper of India, and might next proceed to the Bovine Antelopes or Busdorcinae which form another sub-family of the Bovidae. But those animals, with one exception, and that a doubtful one, viz. *Portax picta* or the Nilgau—are wholly foreign to India, and the Nilgau itself rarely found on the left bank of the Ganges, how common soever across that river all the way to the Deccan Carnatic. Wherefore, having no personal knowledge of the group, I leave it untouched. It will be seen above that my principle of generic classification is organic. I assume that *every* organic variation is a sign of genus, that *nothing but* organic variation is a sign of genus; that we are too ignorant at present of the real nature and use of most organs to decide on their relative value and to reject some because they seem comparatively uninfluential on the habits and economy of the animal endowed with them; that the organ is always, the datum; its use always the desideratum, and that all organs ought to be prominently set forth until their structures, uses, and relative impor-

## SACCHARUM VIOLACEUM.

tance be decided on; that all three sorts of teeth are organs, and all therefore are properly introduced to mark genera and even higher groups; that there is *not* the entire uniformity of dentition among the Ruminants which has been so long asserted; and, lastly, that the special form of the horns in the Cervidæ, though not strictly an organic mark, may yet be wisely used at present to help the indication of genera, because it is a very palpable sign, and one besides usually harmonising with, and indicative of other and organic modifications yet partially or wholly understood. [Note. Mr Hodgson's correction of an oversight in the description of Genus Axis, page 991, reached us after the sheet has been printed off. For "canines in males only," read "canines in both sexes" Eds.]

Ghunna, „	

The Otaheite sugarcane is now abundantly cultivated in the Saharunpore district; but, though it gives a larger per centage of sugar it is objected to by the natives as being too strong for the pressure of the native mill: it is therefore principally cultivated for eating. In the Deyrah Dhoon it has been extensively cultivated for making sugar, and that too with much advantage, but it is there pressed with European mills.

(2702) SAGO OF THE INDIAN ARCHIPELAGO. In most parts of the Indian Archipelago two kinds of alluvial soil are found in greater or less abundance, one consisting chiefly of sand often thrown up in long banks, and the other chiefly of decomposed vegetable matter. The latter is often a consequence of the production of the former, which serves to keep out the waves of the sea, and allow a rank vegetation to flourish. In process of time, by the elevation of the surface and the extension of a similar formation seaward, the older marshes are no longer subject to tidal invasion, and become gradually filled up by the decay of fresh water plants. For these two descriptions of soil nature has provided two kinds of palm adapted in a wonderful manner to the necessities of man. On the barren sand she has planted the cocoanut, and in the morass the sago tree.

The following paper is composed chiefly—1st, of an account of the mode of cultivating and using the sago in the Moluccas translated from Dutch of M. de Steur's (Tijdschrift. Neer I., Ind. 8th year, 3d. part p. 367) adding to it some notices from Valentyn and Forrest. 2d, of an account of the cultivation of sago in Sumatra and the earlier statistics of its manufacture in Singapore, extracted from a paper in one of the early numbers of the Singapore Chronicle. To these we have added, 3rd, an account of the mode of preparing the Pearl Sago of commerce by the

Chinese manufacturers of Singapore at the present day and of the Singapore sago trade.]

- It is to the latter that we wish to direct attention, because along the immense alluvial tract of the Sumatra coast from Siak to the Lampongs, and in the large plains of the rivers of the Peninsula such as those of Rio, Formosa and the Muar, there are hundreds of miles of sago land unoccupied and unproductive, every acre of which is capable of yielding at the rate of about twenty thousand pounds of meal yearly.

The sago tree is found, in one or other of its species, throughout the whole length of the Archipelago, from the islands off the west coast of Sumatra to New Guinea. It is probably capable of flourishing with complete vigour across nearly its entire breadth wherever its natural soil occurs, and certainly within ten degrees north and south of the equator, a band which includes all the Archipelago save the Philippines. The only countries however where it is found growing in large forests are New Guinea, the Moluccas, Celebes, Mindanao, Borneo, and Sumatra, being widely spread over the Moluccas, but confined to particular parts of the others.

The sago does not appear to be indigenous in Sumatra and the Peninsula, which is perhaps the reason why it is titled by the Malays. In the eastern parts of the Archipelago it forms in many places the chief portion of food of the inhabitants. In Singapore we know it principally as an imported article prepared by washing and granulation for the European market. It comes to us chiefly from the adjacent coast of Sumatra and from Borneo, and passes through the hands of Chinese refiners before it is purchased for export to Europe. An account of the production of sago in the eastern and western parts of the Archipelago, the modes in which it is prepared and used by the natives, and the process of purifying and granulating it in Singapore, may help to fix attention on the fact that the Archipelago can furnish any required amount of meal, and that its present high price is owing to the succession of rude manipulations, all attended with wastage and expense, which it unnecessarily undergoes. Instead of being at once carefully washed and cleaned at the place of growth, this work is there performed in a slovenly and in an imperfect manner, but with more labour probably than a thorough purification by a good process would require. It is then packed in small quantities in leafy receptacles and arrives here dirty and sour. The Chinese have now to do the whole work of cleansing over again, with this disadvantage that the farina is no longer fresh. Their process too although far superior to that of the Malays, is imperfect, and involves a considerable waste both of material and labour.

#### *Sago in the Moluccas.*

Amongst all the trees which we have yet mentioned, says Valentyn in his account of the vege-

tation of the Moluccas, there is none more useful to the Amboynese than the sago tree. It shews itself at first, and for a long time afterwards, merely as a bush or shrub, consisting of different upright branches which are about 15 or 16 feet high, green, concave in the inner side, convex on the outer, and smooth. On the lower part of these, long small thorns are seen, which stand in order above each other like needles, the middle being always the longest. The leaves, which are very long and small, stand out on both sides of these branches, are longer, broader, and thinner than those of the cocoanut, and have on the sides soft, erect spines. In due time there rises from this bush a stem, which having reached twice the height of a man, gradually loses its thorns except those above, which also afterwards gradually fall off. The branches which become tolerably thick, have a broad base called gururn, about three feet long and a foot broad, being almost like a gutter which surrounds the stem and the next branch, and decreases to its top. The upper part of the branch is called gabba gabba and is about the thickness of the arm at its top and much thicker below.

As long as the stem is immature, thorny branches at the bottom protect it from the wild hogs who would otherwise fatten on the meal. It gives no fruit until all its strength is expended and its death approaches, and when the branches are strewed with meal, at which time small fruits like round pigeon's eggs shew themselves in great number at its top, like a crown. These are green and when ripe sour, and they finally become yellow.

[Oud en N. O. II. This appears to be *Metroxylon sago*, or *Sagus Konigii*. The following botanical description by Dr. W. Jack, of one of the Sumatra and Malacca species, *Sagus lœvis*, of which the accuracy is confirmed by Dr. Griffith, who adopts it in his paper on the Palms of British East India appeared in the *Malayan Miscellanies* published at Bencoolen:—

This valuable tree rises to the height of about twenty feet, and is generally surrounded by numerous smaller and younger plants which spring up around it after the manner of the Plantain (*Musa sapientum*). The stem, which is about as thick as that of the cocoanut tree, is annulated by the vestiges of the fallen-leaves, and the upper part is commonly invested with their withered sheaths. The leaves resemble those of the Cocoanut, grow more erect, and are much more persistent, so that the foliage has not the same tufted appearance, but has more of the graceful ascending curve of that of the *Saguerns Rumphii*; they are pinnate, unarmed; the leaflets linear, acute, carinate, and smooth. That tree is from fifteen to twenty years in coming to maturity, the fructification then appears, and it soon after decays and dies. The inflorescence is terminal; several spadices rise from the summit of the stem, enve-

## SAGO OF THE INDIAN ARCHIPELAGO.

loped in sheaths at their joint; and alternately branched. It is on these branches that the flowers and fruit are produced, and they are generally from five to eight inches in length. They are of a brown colour, and closely imbricated with broad scariose scales, within which is a quantity of dense ferruginous wool, in which the minute flowers are imbedded and completely concealed. Each scale supports two flowers which are hermaphrodite, and scarcely larger than a grain of turnip-seed. The Perianth is six-leaved, of which three are interior, the leaflets nearly equal. Stamina six, filaments very short; anthers belong, two-celled. Ovaria three, connected together in the middle, each monospermous. Style none, stigma small. Fruit single, nearly globular, somewhat depressed at the summit but with a short, acute mucro or point in the centre; it is covered with scales which are imbricated from the top to the bottom, and are shining of a greenish straw-colour, of a rhomboidal shape, and with a longitudinal furrow down their middle. Below the scales the rind is of a spongy consistence; and the fruit contains a single seed, of rather an irregular shape; and having the umbilicus situated laterally a little above the base of the fruit. The progress of the fruit to maturity is very slow; and is said, according to the best information I can obtain, to occupy about three years from the first appearing of the spadices to the final ripening of the fruit. During the period of inflorescence, the branches of the spadix are brown, and apparently quite bare. Afterwards a number of small green knobs appear above the brown scales, which grow enlarging till they at length acquire the size of a small apple. But few fruit come to maturity on each branch.

In habit and character this tree recedes considerably from the true *Palmae*. Its propagation by radicle shoots, exactly in the same manner as the common cultivated Plantain, is peculiar, and is not observed in the true Palms. The terminal inflorescence and death of the tree after fructification is another peculiarity. It is allied to *Calamus* by its retroversely imbricated fruit.

This species of Sago is abundant in many parts of Sumatra and at Malacca, and is employed in the preparation of sago for food. Considerable quantities are made at the Peggy Islands, lying off the west coast of Sumatra, where in fact it forms the principal food of the inhabitants. The sago of Siak is remarkably fine, and is also, I believe, the produce of this species. At the Moluccas the spinous sort is considered superior to this, but I am doubtful whether it exists in Sumatra.

[Note. The Sumatra plantations contain three kinds, one spinous both on the trunk and leaves "rumbia" (*sagus Konigii*); one spinous on the leaves only, "sanka;" and the other without spines "bumban," which appears to be the female sago or

botanists. Valentyn says the meal of the female sago does not keep so long as that of the other species. He mentions 4 and M. de Steurs 5 species. I. R. L.] For making the sago, the tree must be cut before fructification commences, as it then becomes hard and dry.

The sago tree, whose appearance when it has attained its full growth, has much that of the gomuti tree, is cut down at the bottom of the stem. The greater or less adaptation of the ground regulates its speedy or slow development; its full development may however be placed at about 10 or 15 years. The natives know this period from the appearance of the fruit at the top of the tree, and then call the tree *ma a putric*, (ripe). The tree requires very little care in rearing it, only attention must be given that it is not covered by creeping plants, and, that the foot of the trees be kept somewhat clear of high weeds that the growth of young shoots may not be hindered. A full grown tree of good quality may generally be valued at a sum of f. 8 copper, and a medium tree at f. 5 copper. The sago tree being cut down, the mealy substance inside is taken out and prepared for use and transport in the following manner. The stem is cut with a parang into pieces of a fathom in length, which are split through the middle and cut up, and are always carried with great care to a running water. To separate the meal from the shell, the native uses an indigenous adze, "many," which is of the following description; a piece of bambu 3 inches in circumference and 2 feet long, is pierced with a slanting hole in which another piece of bambu like a chisel, and sharpened at the broad end, is stuck and fastened to the other with a string. For the cleaning of the sago, that is to say, to separate the meal from all impurities and woody particles, an apparatus is used called the *satrany*; it consists of the end of a large old sago stem already properly excavated by nature, fitted at the broadest side by means of bambu pegs to a bag of the bark of cocoanut, "runut;" the *satrany* thus provided, is laid upon two wooden forks about 3 or 4 feet high, the open end being considerably higher and placed under a stream of water running very gently from a bambu pipe, while right opposite the other end a long and a very strong stick is stuck in the ground, and bent till its upper extremity is brought down to the level of the runut to which it is fastened. The runut is thus always kept in a state of tension, when the sago meal mixed with water is pressed by the hand against it. The meal passes through the runut, while the coarse matters, (ela,) remain in the sago trough, and serve as food for pigs and poultry. On the ela when thrown aside in heaps a kind of mushroom grows, which forms an agreeable dish; and when the trees rot there also grow in the rotting parts

## SAGO OF THE INDIAN ARCHIPELAGO.

Worms with brown heads, which the natives roast on skewers, and devour as a great dainty; but the heads are taken off and then they are eaten by some Dutchmen also. But I cannot say how they taste, for I never had an inclination to try them. [*Note Valentyn.*]

The sago pressed through the satrany is received into the "goti," which also rests on two forks stuck in the ground. The goti is a portion of a split sago trunk, of which both ends are made water tight by sago leaves and the spongy substance of gomuti, or the bark of the kaya puti tree. The goti always receives such a supply of water from its upper extremity that it remains full, and gently overflows at the low end, thus allowing the heavy farina to sink, while any woody particles that have been pressed through the runut are carried off by the water.

This simple operation, called pukul sago or striking the sago, being performed, the farina is taken out of the goti and packed in cylindrical baskets made of sago leaves, ready for exportation. These baskets, which are all nearly of the same size, are named "tumang-sago."

It is worthy of remark that the whole of this native mode of preparing the sago, which comes entirely within the reach and understanding of every inhabitant, was taught to the Amboynese by Rumphius who is so well known to them. Before that time the Amboynese, like the natives at this day at various places on Ceram and Buru, and also elsewhere as on the west coast of Sumatra, used the sago mixed with the ela. The recollection of Rumphius is general amongst the Amboynese, and is accompanied by a true recognition of the value of this most necessary mode of preparing an article of food which nature has so bountifully bestowed.

A good sago tree produces about 25 tumangs of meal, which being sold at from 0.75 to 0.80 k. gives the manufacturer a good profit.

The native of the Moluccas prepares the meal in different ways, chiefly however as a hard bread, which, if kept dry, may be preserved as long as our ship's biscuits, and is called sago "lempong." The meal after having been dried for two or three days is sifted until it becomes tolerably fine but remains somewhat adhesive. It is then formed into small flat cakes which, to the number of 7 or 8, are placed in a mould of red earth and baked to the proper degree.

The *sago bornek* or *Borne* granular sago, is dried for a shorter period, then sifted, and shaken by two men in a piece of cloth until it granulates. It is then smeared with fresh cocoanut oil and heated in an iron pan (tatyau) until it attains a certain degree of hardness, after which it is placed in the sun to dry.

A third mode of preparation is the sago tetupala. The meal is aired until it becomes red, when it is sifted, and stuffed into an entire fresh bambu, which is placed in different rows above

a fire until it bursts and the sago is roasted. Sago thus prepared may be preserved a long time if kept dry.

The fourth mode is the "sago buksona." The meal is mixed with grated santang kalapa, sugar, and a little pepper and salt, enveloped in young sago leaves, and boiled in water.

To make the "sago or kwee bagea," the meal, after being dried in the air to redness, is sifted, mixed with fresh kanari kernels, and then baked in young sago leaves. "Sago baruwa" are small sago cakes of different forms. The "sago sinale" is the meal baked to a cake in a pot. The "sago ulu" is the meal enveloped in fresh sago leaves and baked on the fire. "Sago kalapa," like the lemping, is baked in moulds and mingled with much grated santang kalapa; the outside is smeared with gula areng, and it is eaten warm. Sago kalapa is even preferred by Europeans to bread at breakfast, and ranked as a dainty. "Pap-peda," "sago bubur or pap" is prepared in the same way as arrow root.

To proceed to the uses to which the native of Moluccas puts the sago tree over and above extracting from it a wholesome and abundant article of food, we remark that no part of it is lost or suffered to remain unappropriated.

The branches, dried and cut to lengths of 6 to 10 feet and in the state called gaba gaba, soon gain a fine brown, shining colour; the hard shell preserves the spongy interior from destruction when it is not exposed to rain and humidity. The houses are partly and sometimes wholly made of gaba gaba; the best are those of which the frame work is of wood and the sides of gaba gaba. The branches having a concave and a convex side are fastened to each other by small pins, and make as good a wall as planks. Instead of a wall round the yard they also use the gaba gaba, which is made to rest on a low frame work or foundation of stone, and is protected above, by a little atap copping. The gabba gabba placed on a wooden frame work generally lasts from 10 to 15 years.

The leaves of the tree, while still green, are made into ataps, and serve to cover dwellings. When well laid on they last about 7 years. The bark of the tree furnishes a valuable fuel. The stalk of the leaf gives the well known "sapu lidi," like that of the cocoanut and gomuti.

The hard rind or bark of the thicker or lower side of the branch-stem is made into a kind of bucket called gururu, in which the saguwero liquor is collected. From the extremity of the branch, while it is yet very young and green, they prepare a kind of kadas which is used for the sails of native vessels and of orembaais, and also for making the thick and middling sails called ayia ayia. The root of the tree which has been cut down produces new shoots, and is therefore not dug out.

We may remark finally that the Moluccas

## SAGO OF THE INDIAN ARCHIPELAGO.

produce five kinds of sago trees, viz. sago-ihar, with all its leaves depending and full of thorns; sago-tuni with horizontal leaves and less thorny; sago-molat, entirely divested of thorns; sago-makanaru, with leaves somewhat bent down, and sago-rottan, like the last, but with a stem much higher than the other kinds.

Forrest and his crew, during the voyage in the Tartar Galley which he has so graphically described, lived much on sago, and his experiences as an actual sago eater in the Moluccas, enable him to speak with all the knowledge and discretion of a farinaceous epicure. The following remarks by him will therefore complete our notices of sago in the Moluccas.

One tree will produce from two to four hundred weight of flour. I have often found large pieces of the sago tree on the sea shore, drifts from other countries. The sago thus steeped in the salt water, had always a sour disagreeable smell; and in this state, I dare say, the wild hogs would not taste it. The leaf of the sago tree makes the best covering for houses, of all the palm kind [Note. Those trees of the palm kind, have all a heart like what is called the cabbage tree; even the head of the common ratan has a small cabbage, of which I have eat.] it will last seven years. Coverings of the nipa [The ordinary leaf for covering so called.] or common attop, such as they use on the south west coast of Sumatra, will not last half the time. When sago trees are cut down, fresh ones sprout up from the roots.

We seldom or never see sago in Europe, but in a granulated state. To bring it into this state from the flour, it must be first moistened, and passed through a sieve into an iron pot (very shallow) held over a fire, which enables it to assume a globular form.

Thus, our grained sago is half baked, and will keep long. The pulp or powder, of which this is made, will also keep long, if preserved from the air, but, if exposed, it presently turns sour.

The Papua oven, for this flour, is made of earthen ware. It is generally nine inches square, and about four deep: it is divided into two equal parts by a partition parallel to its sides. Each of those parts is subdivided into eight or nine, about an inch broad; so the whole contains two rows of cells, about eight or nine in a row. When the cell is broad, the sago cake is not likely to be well baked. I think the best sized cell is such as would contain an ordinary octavo volume upon its edge.

When they are of such a size, the cakes will be properly baked, in the following manner.

The oven is supposed to have at its bottom, a round handle, by which the baker turns the cells downward upon the fire. When sufficiently heated, it is turned with the mouths of the cells up, and then rests upon the handle (which is now become the bottom) as on a stand.

When the oven is heating, the baker is supposed to have prepared his flour, by breaking the lumps small, moistening it with water, if too dry, and passing it once or twice through a sieve, at the same time rejecting any parts that look black or smell sour. This done, he fills the cells with the flour, lays a bit of clean leaf over, and with his finger presses the flour down into the cell, then covers all up with leaves and puts a stone or piece of wood at top, to keep in the heat. In about ten or twelve minutes, this will be sufficiently baked, according to their thickness; and bread thus baked, will keep, I am told, several years. I have kept it twelve months, nor did vermin affect it in that time. It may not be amiss to mix a little salt with the flour.

The sago bread, fresh from the oven, eats just like hot rolls. I grew very fond of it as did both my officers. If the baker hits his time the cakes will be nicely browned on each side. If the heat be too great, the corners of the cakes will melt into a jelly, which, when kept, becomes hard and horny; and, if eat fresh proves insipid. When properly baked, it is in a kind of middle state, between raw and jellied.

A sago cake, when hard, requires to be soaked in water, before it be eaten, it then softens and swells into a curd, like biscuit soaked; but if eat without soaking (unless fresh from the oven) it feels disagreeable, like sand in the mouth.

No wonder then, if agriculture be neglected in a country, where the labour of five men, in felling sago trees, beating the flour, and instantly baking the bread; will maintain a hundred. I must own my crew would have preferred rice; and when my small stock of rice, which I carried from Balambangan, was near expended, I have heard them grumble, and say *manti makan roti Papua*, "we must soon eat Papua bread." But as I took all opportunities of baking it fresh, being almost continually in port, they were very well contented.

The sago bread intended for immediate use, need not be kept so long in the oven as what is intended for sea use, which may be said to resemble biscuit.

I have often reflected how well Dampier, Furnel, Roggewein, and many other circumnavigators might have fared, when passing this way in distress for provisions, had they known where to find the groves of sago trees, with which most islands here in low latitudes abound; Morty, near Gilolo especially. Fresh bread made of sago flour, and the kima (a large shell fish like a cockle) would have been no bad support among the Moluccas. The kima is found in abundance, of all sizes, at low water, during spring tides, on the reefs of coral rocks. From experience, I equal the fresh baked sago bread to our wheat bread; and the kima stewed, is as good as most fish, nor does one tire of it; but it must be

## SAGO OF THE INDIAN ARCHIPELAGO.

blew some time, or it will not be tender. Its roe will sometimes weigh six pounds; the fish altogether, when cleared of the shell, weighing twenty or thirty pounds.

The *Sago of Sumatra*. From the Singapore Chronicle.

Low marshy situations shut out, but at no great distance from the sea, and well watered by fresh water seem most productive. The soil in such situations to the depth of several feet is generally a flaccid mould, composed chiefly of decayed vegetable matter and extremely pervious to water, below the above depth a stratum of marine formation generally exists. According to Raffles, in Java this tree is found only in a few low marshy situations, and the preparation of sago from the nature of the soil in the places we have mentioned is very similar, all of them being deep bogs, next to impassable to one unaccustomed to such walking.

Cutting down and burning the jungle is all the preparation required previous to planting the palm, at about 5 fathoms apart, which is best done from the seed, a small black nut, about the size of a pullet's egg.

Plantations have been tried from the suckers, but the injury sustained by their roots in the separation from the parent stem has invariably retarded their growth above a year.

From seven to ten years is the time it takes for the tree to bear fruit, when planted from the seed in the first instance; the pith commences generally at about the age of 6 or 7 years; after this period, it gradually loses its moisture, and is no longer fit for sago when the tree comes into bearing.

Sago is cultivated in large patches, divided into lots the property of individuals, and as much as one man, his wife and family choose to look after: I say choose, because it is not as much as they could if they would attend. One man as above can manage 100 fathoms square, upon this he plants 400 seeds, and subsists himself for the first 6 or 7 years on his means, not unfrequently leaving the trees to take care of themselves, until he can commence the pith is not known to the inhabitants." Marsden says that sago is but little used by the Sumatrans, and Crawford presumes that in this, or the Western part of the Archipelago, the sago palm is an exotic. Our enquiries have been unavailing in the attempt to discover it to be indigenous in our neighbourhood, and we feel confident that it does not exist in the native wild state to the westward of Borneo.

The best sago produced in our vicinity, is from the Islands of Appong and Panjang, which form the East bank of Brewers Straits or properly Salat Panjang, and next in quality, is that from the rivers Mandha, Kataman, Goung Egal, Plandok, and Anak Sirka, lying between the Kampar and Indragiri rivers, on Sumatra, or Pulo Percha,

as it is called by the Malays. Of least value is the produce of the islands of Buru, Ungah, and Kundor, in the straits of Dryon or Salat Duri. The sago palm is found in several other places in small quantities, but is seldom cut down by the lazy possessors of it, to whom it probably descended through a long line of equally sluggish ancestors, from some Inchi of zaman daulu, who had better notions when he planted it. The native commence cutting. From that day the supply is constant, each tree throws out from 10 to 20 suckers, which increase so rapidly that the owner is obliged to thin them constantly. A good tree yields from 40 to 50 tampins, and the worst ever cut down about 25; this is on Appong. The Tampin of Appong is to that of Mandha as 4 is to 5. It is a rough measure made of the leaves of the sago tree of a conical form 20 to 30 inches long with a base of about 8 inches diameter both ends of this are stuffed with the refuse pith to prevent the escape of the farina, and the tampin of Appong holds on an average 19 pounds avoirdupois—thus 7 tampin very nearly equal a picul of this place, or 133½ lbs. avoirdupois.

It will be needless to speak of the sago of each place, differing but a little in quality, and in the measures they are sold by, as the acuteness of the Chinese brings them all to their true level on arrival here. One remark on the stupidity of the cultivators may be made, viz., that 100 tampins of Appong may always be purchased on the spot, cheap or dear at other places it matters not, for 6 l-4 reals or Sp. Drs. 5-12 as a Sp. Dr. or a Real is the same thing with them and both go alike for 244 doits or 82 cents of a Sp. Dr. of Singapore. If the person in quest of sago takes doits, they must be of the small kind, but thick. At Mandha, on the same principle the same number of tampins may be had for Sp. Drs. 9-61. Now the Appong measure yields 14 piculs 29 catties and the Mandha 17 piculs 86 catties; being a difference against Appong of Sp. Drs. 2 51, and all because they say it has been the adat or custom to sell it so.

One person is sufficient to clear the underwood away as it grows up in every lot of 100 fathoms square. The whole family are however fully occupied when they cut down the trees for manufacture which is always done on the spot where the tree is felled. They prepare the number of Tampins or measures required for the reception of the sago in the first instance, and put them out to dry; they then fell the tree, and split it in halves by means of wedges, build a temporary house over it and dig out the pith with hoes made from the rind of the tree. They then carry the pith up into the house; the floor of which is latticed so close as just to allow the finer parts of the medulla to pass through on being wetted with water and trodden by the feet. Into this house the produce of two or three trees

is brought at a time, and all the finer parts are carried down by the water into the trunks of the trees, [Note. A boat is often used.] 3 or 4 feet in diameter which are cleanly hollowed out and left below to receive it. In order that no wastage may take place, they lead a mat, made also of the leaves of the palm, from the floor of the work shop down into the shells of the trees, and this carries the water without spilling any. They trample it until the water passes through clear of the farina, and then throw away the refuse, keeping sufficient merely to stuff the ends of the tampin. By the next day, the medulla has settled in the trunks of the trees, leaving the water at the top; this is drawn off and the sago flour thrown in its wet state into the tampin already prepared, and left to strain itself: some refuse pith is then put on the end, before left open, of the base of the cone, and the work is done. The shell of the tree is cut up for firewood or in slips and thrown into the marsh, to prevent the poor devils going quite overhead in carrying down the sago to the boats waiting for it. This is always their duty, for if the Malays who come to purchase could not get this included in their agreement the chances are they would go elsewhere in search of the sago. Sago once made is obliged to be kept wet or it would spoil in a few days; again, kept constantly wet the tampin leaves soon rot; cultivators cannot therefore keep a stock ready, but at greater risk than these savages choose to undergo. They have a method of frying the meal over the fire called there sago randang, which sells for a real or 82 cents of a sp. dollar, for 16 of their gantongs are equal to 20 of Singapore or one picul. This however will not keep long; as damp throws it all into a glutinous mass and in a short time spoils it, and it may easily be supposed that their situations are not very dry and airy. At Appong the sago is made by Orang Utan or people of the woods, who speak a jargon of Malay, are not Mahometans, and eat the hogs, deer, &c, with which their island abounds. The maritime Malays who visit them for sago, are obliged to be always upon their guard, and not unfrequently wait 2 months for a cargo of a few hundred tampins; if they take money to purchase they get it much quicker, but require additional caution in making advances. There are said to be about 350 souls, and that the produce might be put down at 3,000 piculs a year. Most of these people are dependants of Siak and Campar, the chiefs of the former place practising a system of extortion and rapine enough to induce any other class of people less accustomed to it to desert the place. [We lately found two families on Battam, they had managed to make their escape,—J. R. L.] The cultivators in the other places are Malayas and much superior, though their exports are severally less, and trafficking with them is not so dangerous or uncertain.

Appong has 350 souls employed and could produce 3,000 piculs. This would afford under all the disadvantages at which they sell it Sp. dollars 1,024 per annum a sum quite adequate to the demands for foreign luxuries of people who do not eat rice, and live upon the produce of their woods. The people of Siak were the chief importers of sago into Malacca, whence erroneously it got the name of Siak sago described as the best by Crawford: Siak itself exports no sago.

Malays all agree that the cultivation of sago is the most profitable of agricultural pursuits, not yielding even to the cultivation of rice by Sawas, for once in bearing the trees are ad infinitum equally profitable and require little or no labour.

The miserable state of barbarism in which the cultivators of sago exist, puts all calculations at defiance, but we do not hesitate in saying that if any person would commence here, and there are many places peculiarly favourable to it and of considerable extent, the profits of an English acre when the trees were once fit to cut would amount on a low estimate to 50 pounds sterling per annum after paying all expenses.

This too is a branch of agriculture that an European might engage in without the certainty of being robbed, which pertains to the culture of spices &c.

The maritime Malays, who are almost the sole importers of sago, are enabled generally to realize from 80 to 120 per cent. on their cargoes: they are seldom ten days at sea, and notwithstanding the occasional detentions and annoyances they experience in carrying on this traffic, must, with few exceptions, be well recompensed.

Allowing an absence of two months, in a boat of two coyans, and five men, bringing back four hundred Tampin, they have a clear gain on their return cargo of 17 to 26 dollars according to the state of the market, giving each person a profit as wages, when sago is in demand, of two and a half Spanish Dollars per month, and putting a side 50 cents for wear and tear of the boat, a sum quite adequate for this purpose independent of the preference which people bred up to a sea faring life, generally give to it over all other modes of more profitable subsistence, and setting aside the chance of again which they have on their cargoes imported into the sago districts.

It is curious to contemplate the natural prices fixed by the two classes who cultivate sago. From what we have before stated, it will appear that the rude inhabitants of Appong, by calculation of their wages of labour and profits of stock, on a reduced scale compared with their more civilized and wealthier neighbours, the Malays of Mandha and other places, have contented themselves with an average rate about 30 per cent less, evidently arising from their poverty and barbarous condition.

We have no data from which to compute the

## SAGO OF THE INDIAN ARCHIPELAGO.

even probable time at which the sago tree was introduced into our vicinity ; connections have existed for ages amongst the people of this part of the Archipelago, and the Eastern Islands, which though not perhaps purely commercial, were yet sufficient to have brought this about affording at once as it does, a livelihood and subsistence, without the possibility of a scarcity requiring little labour beyond planting the seed, and of all others most easy of attainment and agreeable to the scale of Malayan industry.

The most satisfactory conclusion we can arrive at in the above speculation is, that when or how introduced it matters little, since it will be evident, that of late years only it has acquired any consequence as an article of commerce. It has lain dormant from various causes, among the most evident of which appear to have been the want of purchasers from the grower, even Malays themselves of other parts being formerly afraid to visit them,—the attendant difficulty of getting it to a market, Malacca being the only one except Penang, which previous to the establishment of Singapore was at too great a distance, besides the risk of meeting Pirates on the voyage,—and again, the naturally slothful disposition of cultivators which operated effectually in keeping down the produce, until of late years, when Singapore, in a great measure removing the above obstacles, has created a stimulus to exertion, more probably on the steady increase than the decline, great as the demand now is.

### *Manufacture of Pearl Sago in Singapore, by Chinese.*

The greater number of the Singapore manufactories are placed on the flat ground between the basis of Pearls and Oo Long's hills and the winding and branching creeks and canals of the Singapore river, a situation admirably adapted for them, for the creeks bring the sago boats up to them in front and the hill supplies them from behind with an abundance of pure water. To procure a constant supply, wells are dug on the lower slope of the hill, and the water is led into the manufactories by a succession of wooden troughs having their bottoms lined with clay and which are supported by cross sticks fastened at the place of contact by rattan. The essential features of every manufactory are, the landing place where the sago is taken from the boats, a rude shed where it is removed from the sago leaves in which it is enveloped, a second shed where it is purified, and the large house where it is formed into pearl sago. Besides the tables, furnaces, and bins required for the sago, the latter contains the beds, stools and dining tables of the workmen, and occasionally heaps of boxes. Hitherto it has been an attap shed roughly put together and often only partially closed at the sides. But some of the more wealthy manufactures are now raising substantial edifices of brick

and tile, and it is to be hoped will also introduce into their establishments a little attention to cleanliness and comfort. At present the mass of decomposing vegetable matter which surrounds the sheds produces a sour disagreeable smell. The sago leaves and refuse accumulating in some places for the last 50 years, have there formed extensive beds, spongy at the top and solid below six or seven feet in thickness.

The tampins having been placed in heaps in the shed, the first step is to open them, cast the contents on a plank frame about 12 feet square, surrounded by a rim rising about 2 inches from the surface. The sago, massed together by having remained compressed in the tampin, is here broken up by the common chunkal, a kind of hoe.

The raw sago having been thus made ready for the manufactory, the first process to which it is subjected is that of a thorough washing, without which it would remain impure and coloured. For this purpose strong tubs are employed, about 32 inches deep, 40 inches in diameter at the top and 6 inches more at the bottom ; they are bound by three hoops, each formed of about six thick rattans twisted together. A piece of thin coarse cloth is fastened by its four corners over each tub when used, and hangs loosely into it. The moist sago being poured into this strainer, and there broken and bruised by the hand, is agitated until all its fine particles pass through the cloth and descend to the bottom of the tub, while the fragments of leaf, fibre and other impurities which remain in the cloth, are shaken into a round mass, which is taken up in a bowl and thrown aside. The rapidity and deftness with which this and all the other manipulations are performed are very striking. The sago is next stirred about with an oar for about an hour, after which it is left to stand for about 12 hours, when the water is ladled out, and the sago, which fills about half the tub, is removed to undergo the last purifying process which precedes the granulation. This is performed in a mode at once simple and ingenious, the same principle being availed of which serves the gold and tin miners of the Archipelago to clean the ore ; the more precious matter happening, in all three cases, to be heavier than that with which it is mixed ; and being thus readily separable by the action of running water.

Two tubs are placed at a distance of ten or twelve feet from each other, and connected by two troughs raised by a frame work above them. These troughs are about 10 inches deep, 14 inches broad at the top and 11 at the bottom, one end being closed, and the other open, but having grooves in its sides and bottom, like those of a sluice, into which a series of horizontal pieces of wood or sticks fit, each being about  $\frac{3}{8}$ -ths of an inch in thickness. The end of a piece of cloth of the breadth of the trough being placed over

## SAGO OF THE INDIAN ARCHIPELAGO.

the grooves at the bottom, the shortest of the sticks is pressed down upon it, and the cloth, thus fastened, is made to hang down over the edges of the trough into the tub below it. The tub at the other end now receives the sago to about two-thirds of its depth, when it is filled up nearly to the top with water. A man now stirs up a portion of the sago with an oar till the water obtains a milky appearance, when he proceeds to pour it into the troughs. To prevent its falling abruptly, an inclined piece of wood, eight inches broad, is fixed across the trough, so as to leave only a narrow slit between it and the end of the trough. The water is poured on this, descends into the trough, and slowly flowing to the other end deposits a portion of the sago in its progress. The suspended cloth, becoming saturated, serves at once to maintain and equalized the overflow of the water into the tub below it. When the water is poured in, the first waves advance rapidly and carry away much of the sago, but those that succeed deposit the greater part of their more solid contents, transporting into the tub only the lighter fibrous particles which it is the object of this operation to separate from the farina, and by the time the man has performed a similar service at the other trough, and is ready to pour a fresh supply into the first, the water flowing down the cloth has lost its whiteness. This process is continued until the deposit rises nearly to the level of the stick, when the sago next to it, which generally contains some impure sediment, is taken up with the fingers and thrown into the tub. The second stick is now fixed above the first, a fold of the cloth being interposed between them to prevent any liquid sago escaping though the seam, and the operation goes on as before. When the milk in the upper tub begins to grow shallow, it is again filled up with water and more sago stirred up and mixed with it. During the interval and at other more prolonged interruptions the water in the troughs has sometimes time to deposit all its contents, the last being a fine fibrous matter which, if not removed, would leave a thin yellow layer. The surface is washed with the hand until this layer is effaced and held in suspension. When the troughs have been gradually filled up in the manner described, by succession of deposits, and the wall built up to the top by the last stick, the sago is left to consolidate for 12 or 14 hours. The farina which passes out of the troughs in the current is afterwards thrown into one of the tubs whose contents are to be washed and deposited in their turn, and some of it may even be destined to pass through the process many times before it sinks in the trough.

In order to give it the degree of dryness required, it is removed from the troughs and exposed for one day to the sun in lumps about a cubic foot in size, which are placed on tables standing

in the open air. Large kajangs [Note. Mats made of the leaf of the mangkwang.] are kept in readiness to cover it when a shower of rain falls. It is next carried to the large shed where it is thrown in a heap on a long table and broken down into a pulverulent state. It then passes through an oblong sieve, 30 inches by 20 inches, of which the bottom is formed of paralld fibres from the stem of the cocoanut leaf, kept in their positions by strings which cross them at distances of about 2 inches. The lumps which do not pass through the long interstices between the fibres are thrown back into the heap.

The granulation or pearling now takes place. The sifted sago is placed in a cloth of which the ends are tied to a long stick and which is kept expanded in a bagshape by a short cross stick. A horizontal vibratory motion is given to this, the whole mass being kept in constant agitation, and every part successively driven along the sides of the bag. [Note. Some experience is required in drying the sago to the proper degree preparatory to granulation. If under dried or over dried it will not granulate.] This lasts for about a minute, when the new granular sago is again passed through a sieve similar to the preceding one, but the smaller grains which pass through are those which are now rejected. Those that remain are transferred to a circular sieve, of which the bottom is formed of fine stripes of bambu crossing each other. The grains that pass through the square holes thus produced form the pearl sago of commerce in the unroasted state. Those that are larger than the holes are thrown back into the heap to run through the same course again. To assist the men the oblong sieves and the granulating bag are sometimes suspended by rattans from the rafters of the shed.

The roasting takes place in a row of iron pans, each about  $2\frac{1}{2}$  feet in diameter, which are built into a platform of masonry about 15 feet long and 4 feet in breadth, covered with flat tiles. The pans rest in an inclined position partly against the back of the platform which rises about a foot above its level, and partly on a small prop of brick work on the right side, an offshoot from the wall. Into the top of this prop a plate is sunk in which a cloth saturated with wood oil [Minia krueng,] is kept. Behind each pan is an open furnace mouth, and a man constantly attends to the fires, keeping them supplied with a few billets of bakauwood, and regulating them with a long two pronged iron fork so as to maintain a moderate heat. The pan being gently rubbed with the cloth a man who sits in front of it on a low stool placed on the platform pours into it a quantity of granular sago. This he slowly stirs for a short time with a wooden implement called "weah" having a sharp curved edge. More sago is poured in until it amounts to about two chupas, when as it hardens he uses the weah more freely.

## SAGO OF THE INDIAN ARCHIPELAGO.

After about three minutes roasting, it is removed to a table and passed through a round sieve similar to that before described. The grains that adhere to each other are thrown aside, and those that pass through form a smoking heap which is allowed to lie undisturbed for about 12 hours. The grains are about the same size as they were before roasting, and some retain wholly or partially their white and mealy appearance, but the greater part having become translucent and glutinous, and all have acquired a certain degree of toughness, although still soft. [This change appears to be brought about in this way. The water contained in the granules being heated first converts the mealy starch into a jelly and then escapes by evaporation, leaving the jelly tough. The second trefaction drives out the remainder of the water.]

The final process is another roasting, which renders them hard and tough, and greatly reduces their size. The pearl sago thus prepared and fit for exportation, is put away in large open bins ready to be transferred to boxes or bags when sold.

The method of making pearl sago which we have described appears to have undergone no improvement or change whatever since it was introduced into Singapore in 1819. One of the oldest manufactories informs us that it was taught to the first Chinese who tried it here, by a woman who came from Bukit Batu, a place on the coast of Siak facing the large island of Bencolin, and famous for its great fishery of the trubu, the roe of which is so extensively used. We should rather have supposed that it was introduced into Singapore from Malacca, where manufactories had existed for many years before the establishment of Singapore. It is certain however that Malacca derived the art from Bukit Batu, where it originated about the beginning of this century. It was long kept secret, - but in Singapore it appears almost from the first to have been conducted without any attempt at concealment.

From 20 to 30 men are employed in the larger manufactories, but if their labours were confined to the making of pearl sago, 16 men would suffice for a manufactory such as we have described above, and they would produce about 450 piculs per month. Their wages are, for the roasters and the man at the troughs 4 dollars, and for the other men  $2\frac{1}{2}$  to 3 dollars a month, and they receive their food besides. The original outlay is probably from 300 to 400 dollars. The profit of course varies greatly; and the business cannot be so certainly lucrative as has been sometimes supposed, since there have been instances of failures. There are at present fifteen Chinese manufactories in Singapore, and two have recently been commenced by Europeans. We doubt their being able to compete successfully with Chinese, unless they can introduce a more perfect washing

and granulating process, that adapted at present requiring so much labour, and being attended with so much waste, that unless the full work be got from the Chinese employed, there will be little room for profit. The Chinese method of preventing all loss of labour which they carry into most of their undertakings is brought into the sago concerns also. One of the principal shareholders lives in the manufactory, and the best workmen have small shares in the profits besides their wages.

*The Trade in Sago.* We have seen that a large portion of the sago imported into Singapore is the produce of the marshes of Siac and Indragiri, the low island of Rantan containing the most extensive plantations. It is purchased in Siac from the Malays and Orang Sakai by Malays, chiefly of Siac and Singapore, who resort there in small boats for the purpose. In their hands its cost is enormously enhanced, the Sakai selling it to them at about 10 cents per picul, and they selling it to the Singapore manufacturers at from 70 cents to one dollar per picul. [Note. The plantations belong to Malays who employ the Sakai as serfs in planting them and preparing the sago, allowing them one half of the produce. On this and wild animals they subsist, and the sago which they do not require they dispose of to Malays in barter for cloth, tobacco, &c. The Malays admit that by this mode of dealing the sago does not cost them much more than 10 cents per picul. This entirely agrees with the system adopted in their dealings with the Binua of Johore—*Jour. Ind. Arch.* Vol. 1.] The Malays at the Siak islands, and at the sago plantations between Kampar and Indragiri where they have no serfs, sell the sago on the spot at about 20 cents per picul. The price obtained by the latter for pearl sago was at first 6 dollars per picul. The Singapore Manufacturers having succeeded in improving its quality by a more careful manufacture, and the demand increasing for export to Europe, the price rose in 1824 to 7 dollars. This caused the establishment of several new manufactories towards the end of that year which at once brought it down to  $5\frac{1}{2}$  to  $6\frac{1}{2}$  dollars. In 1825 the supply exceeded the demand and two of the principal manufactories, one of which had employed 55 men, were abandoned, and the price fell to 4 to 5 dollars. In 1826 it descended to  $3\frac{1}{2}$  dollars to 4 dollars, and by 1831 it was  $2\frac{1}{4}$  to  $2\frac{1}{2}$  dollars. In 1838 it was so low as dollar  $1\frac{1}{4}$  to  $1\frac{1}{2}$ . After this it rose again. In 1845 it was about 3 dollars. It is now about 2 dollars 65 cents, and has for several years remained between 2 and 3 dollars.

The importations during the earlier years of the Settlement were as follows:—

1819—22 boats, quantity not ascertained,  
1820—5,684 piculs.

# SAGO OF THE INDIAN ARCHIPELAGO.

1821—10,694.  
1822—11,445.  
1823—no imports.  
1824—11,669.  
1825—25,612.  
1826—21,666.  
1826-27—17,768.  
1827-28—16,205.  
1828-29—15,818.

The following tables, for which we are indebted to the honorable the Resident Councillor, will shew the state of the trade for the last 5 years as far as the records of the Office of Registry of exports and imports can be relied on, having been carefully prepared by the indefatigable Deputy Registrar, Mr. Holloway. The average of the exports for that period is about 16,000 piculs of sago flour and 24,000 piculs of pearl sago, or a total annual export of 40,000 piculs, of the value on the spot, at present prices, of 160,000 dollars:—

## RAW SAGO.

					Bundles.
To Borneo, .....	...	...	...	...	100

Low as the price of sago has fallen, we need hardly point out, after all the data which we have placed before our readers, that it is still much above its natural amount. It is not an article which can ever displace the cereals, or which we could wish to be anywhere substituted for them, but it ought to be produced in an exportable state at such a price as to be within reach of the poorer classes, whenever a diminution in the supplies of rice or corn deprives them of a sufficient quantity of their ordinary food. This could easily be accomplished by Europeans possessed of a little mechanical skill, who would combine manufactories and plantations, and thus save the present enormous waste of labour and raw material, 25 cents per picul seems to be about the natural price of sago flour properly prepared at the plantation for exportation, and this is nearly equivalent to 10 pounds for a penny. We have seen that at present the poor Sakai get only about a half penny for that quantity.

Singapore itself is well adapted for sago. There are considerable tracts of marshy land at present lying waste, in all of which sago would grow well, for it is in the very same kind of soil that it flourishes in the neighbouring islands along the Sumatra coast. Arrow and other roots yielding starch are now cultivated with profit, and as one manufactory will serve for the preparation of all the varieties of farina, it would be found advantageous to unite the culture of these roots with that of sago. As all the marsh vallies in the island are bounded by low hill ranges, tracts of land adapted for the purpose could readily be selected.

*Note on the mode of growth and productiveness of the sago tree.* The notices in the above paper of the mode in which the sago tree extends itself not being so definite as could be desired, we visited three groups of sago, one on a moist clay soil at the foot of Syed Ally's hill, and the others in a soft vegetable soil behind the village of Kallang. The first is a dense, impenetrable thicket of sago plants, each of which rises directly from the ground. Three stems ascend above the mass of leaves, a few younger plants send up leaves about 15 feet high from stoles about a foot in breadth, and the whole space between them is filled with younger shoots as close to each other as they can grow. The Kallang trees present a different aspect, owing to the soft, loose soil. The largest of the two groups is evidently of considerable age, and is in reality one connected tree. From a central point six thick roots spring which spread along the ground in different directions to the distance of 6 to 8 feet, when they bend upwards and rise into trees. From these trunk-like roots numerous rootlets descend into the soil, while large branch roots strike out laterally from which other trees rise. At present there are 4 large stems, and 14 young trees of different sizes rising between them and sending up lofty leaves, but without any stem. Around the stole of each of those a great number of shoots are constantly springing, each capable of becoming a tree if it had room. The hollow bases of some trunks which have been cut down are seen. The growing stems are about 16 inches in diameter and covered with moss and small ferns. About the middle of the space covered by this multiplex tree no shoots rise, the oldest parts of the roots appearing to lose their productive power.

The other trees is younger, the large roots having only extended 3 or 4 feet from the centre and still preserving their full vigour throughout, for while each has a tree rising from its extremity, a thick growth of shoots extends along both its sides.

Forrest states the average produce of a Molucca tree to be 336 pounds, but Rumphius makes it from 600 to 800 pounds, and according to the writer in the 'Singapore Chronicle,' who seems to have paid great attention to the subject, good Sumatra trees yield from 760 to 950 pounds, and the very worst 475. Perhaps therefore 700 pounds may be assumed as an average for the Sumatra trees, which at 10 feet apart (the distance stated by Forrest and followed by Crawford would give about 200,000 pounds for the harvest from one acre, and, allowing that the harvests are 15 years apart, and not seven as Forrest assumes, this will give an annual average produce of about 20,000 pounds. We believe however that 5 or 6 feet is about the average distance of the large stems in the Sumatra forests. When a plantation has once arrived

## SAL-GIRIH.

at maturity there will be a constant harvest, because the natural mode of growth secures a continual succession of new plants from the time those first planted have begun to extend their roots, and, this succession can be regulated by the knife in any way the planter desires. The sago tree when cut down and the top severed from it, is a cylinder about 20 inches in diameter and 15 to 20 feet in height. If we assume 20 inches by 15 feet to be an average size, the contents will be nearly 26 bushels, and allowing one-half for woody fibre there will remain 13 bushels of starch, which agrees very closely with our previous calculation, 700 pounds being equivalent to  $1\frac{1}{2}$  bushels. It may give some idea of the enormous rate of this produce, if it be considered that three trees yield more nutritive matter than an acre of wheat, and six trees more than an acre of potatoes. An acre of sago, if cut down at one harvest, will yield 5,220 bushels or as much as 163 acres of wheat, so that, according as we allow 7 or 15 years for the growth of a tree, an acre of sago is equal in annual produce to 23 or 10 acres of wheat.—*Jour. of the Indi. Archi. Vol. III. No. V., May, 1849. page from 288 to 313.*

(2703) SAKI MATI. The coarse kind of barilla (*Saji mati*) to which Dr. Royle alludes, p. 319, as the produce of the incineration of some unknown plants, is a mineral product very abundant near Monghyr and in the Dooab.—*O'Shaughnessy, page 525.*

(2704) SAKUNTALA, name of a Sanscrit Book.

(2705) SAKYA TRIBES, OR SACÆ. The epoch of Sakya (the fifth Buddha or Gautama) is determined by concurrent testimony of the Ceylonese, Siamese, Pegu, Burmese and Chinese eras, which are all founded on the birth or death of the Buddha legislator, and though all differing more or less, concur in placing him between the limits of 544 and 638 years before Christ. The Raj Guru of Asam, a pandit well versed in Buddha literature, fixes the Nirwan or emancipation of Sakya Muni in 520 B. C.

According to Mr. Cosma de Koros, the name of Kanishka occurs in a Tibetan work as a celebrated king who reigned in Northern India, at Kapila, which is supposed to be in Rohilkund or near Hurdwar. His reign dates about 400 years after Sakya (about the end of the second century) when the followers of the Buddha religion had become divided into eighteen sects (the Sakya tribes, or Sacæ) under four principal divisions, of which the names both Sanscrit and Tibetan are on record.—*Prin. Ind. Ant. Vol. I. p. 39.*

(2706) SAL-GIRIH. PERS, or Burrus-ganth, Hind. the anniversary of a person's birth on which a knot is added on a string kept for the purpose.

## SALT.

A girl's years are numbered by a silver loop or ring being added yearly to the gurdonee or silver neck ring.—*Herkl.*

(2707) SALIGRAMS are fossil ammonites obtained from Northern India. The saligram is held in high estimation by Hindoos. Mr. Colebrook, in the 'Asiatic Researches,' vol. vii. page 241, says that these stones are found in a part of the Gunduk river, within the limits of Nepal. Major More, in his 'Hindoo Pantheon,' says they are black, mostly roundish and commonly perforated in one or more places by worms, or, as the Hindoos believe, by Vishnoo, in the shape of a reptile. Others are violet and oval. The possessor of a saligramu, observes the same gentleman, "preserves it in a clean cloth; it is frequently perfumed and bathed, and the water thereby acquiring virtue is drunk and prized for its sin-expelling property." It is always placed near persons when they are about to die.

(2708) SALIX BABYLONICA. Weeping willow.

Mujnoo, HIND.

(2709) SALIX ÆGYPTIACA.

Bed Mooshk, HIND.

From the flowers of this willow the Natives of Northern India, make a kind of sherbet, which is much drunk by them in the warm weather.

(2710) SALIX TETRASPERMA.

Bhynsh, HIND.

(2711) SALMALIA MALABARICA. Pooleo Marum, Tamil. Common about Nelumbore in Wynaad where it is used for building.—*McIvor. M. G.*

(2712) SALT. A brine spring exists at Dyhunda, North Berar, from which salt is manufactured. There are also salt springs near Prome, in Pegu, from which salt is made. In Bellary salt is manufactured from saline earth in the same way as saltpetre is procured; only in the salt manufacture the water is not boiled. It is extensively consumed in the district, though the people prefer sea Salt, the greater cost of which is however a bar to its use.—*Cat. Mad. Ex. of 1857.*

Salt is extracted from the saline soils of several parts of India and used as a condiment. The Natives of the Bellary and Cuddapah districts of the Peninsula, and those of Ghazipoor in the villages of Tuttalapore, Ratouly, Sahory, Chilar and Becompoor all in this way obtain a useful condiment.

Bengal. The supply of salt in Bengal is provided partly by manufacture, conducted on account of the Government. The manufacture is carried on, not by hired labour on the part of the Government, but by a system of pecuniary advances; the parties receiving them, being bound to deliver, at a fixed price, all the salt manufacture. Probably 100,000 labourers (called

## SALT.

molunghees) are engaged in the manufacture in the Sunderbunds. Partly also by importation, and in one instance as with Mr. Prinsep's salt-works at Narriarpore, partly by private manufacture, under a system of excise. The duty is levied at the time of the clearance of the salt from the bonded warehouses. On all imported salt the duty is two and a half rupees per maund of 82 lbs., or about three farthings per lb. The same rate of duty is levied as excise on salt manufactured by private individuals; and the Government salt may be purchased at all times in quantities of not less than 50 maunds, at a fixed price, which is composed of the cost price, with the addition of two and a half rupees per maund, or three farthings per lb. The salt agencies are located along the head of the Bay of Bengal, viz., at Hidglee, Tumlook, Chittagong, Arracan, Cuttack, Ballasore, Khoredah. The average cost price of production is about Rs. 80 per 100 maunds, or a trifle below one farthing per lb., thus making the government selling price under a penny per lb. The supply of salt is no longer a monopoly; its manufacture and sale have not been relinquished by Government, but individuals participate in its provision, both by importation and manufacture, under a combined system of customs and excise.

The system of *fixed prices* and *open warehouses*, commenced in 1836-37, when the previous system of *fixed quantities* and *periodical sales* was abolished, [as recommended by the Select Committee of the house of Commons in 1836.]

Maunds of 82 lbs.

During the seven years commencing with 1837-38 and ending with 1843-44 the duty on salt was Rs. 3-4 as. per maund. The annual average quantity of salt sold and imported during that period was.....	4,627,030
In November, 1844, the duty was reduced to Rs. 3 per maund, and the annual average sale increased to .....	4,966,917
In April, 1847, the duty was further reduced to Rs. 2-12 as. per maund, and the annual sale amounted to.....	5,452,900
In April, 1849, the duty was again subjected to reduction, when it was fixed for five years at its present rate of Rs. 2-8 as. per maund.	

It will thus be seen that in the five years above adverted to, the reduction effected in the salt tax amounted to nearly 25 per cent.; but it would appear that no further reduction can, for the present, be expected consistently with the maintenance of the revenue, the last reduction in 1849 having led to no further increase of consumption.

## SALT.

## NORTH-WESTERN PROVINCES.

The supply of salt to the North-West Provinces is furnished partly from the lower provinces of Bengal, and partly from the Sambhur Salt Lake, in Rajpootana, and other localities on the western side of India. The salt of Bengal having paid the excise or import duty of Rs. 2 as. 8 per maund, passes free into the North-West Provinces. The Sambhur and other salt, on crossing the north-western frontier customs line, is subjected to a duty of two rupees per maund, and to a further duty of half a rupee per maund on transmission to the eastward of Allahabad, thus coming into competition with the salt of Bengal under an equal duty of Rs. 2 as. 8 per maund.

*Madras.* At Madras salt is manufactured on account of Government, and sold for internal consumption at one rupee per maund, or under one farthing per lb. The duty on imported foreign salt was three rupees per maund, but it has been recommended by the home authorities that the import duty should (as in Bengal) be equal only to the difference between the selling price and the cost of manufacture; the difference between the cost price and the price at which the salt is given out for consumption being the duty to be realized.

*Bombay.* In Bombay the manufacture of salt is carried on by individuals, but subject to an excise duty of twelve annas (1s. 6d.) per maund, a similar duty being imposed on imported salt. Salt exported from this presidency to Calcutta is subject to the above excise duty, but credit for that amount is given at Calcutta in the adjustment of the local duty. Facilities are also afforded for the export of salt to Malabar, Travancore, Cochin, and other places.

*Punjab.* The excise duty on salt at the Punjab Salt Mines has been fixed at two rupees per maund.

English salt, it is said, may be laid down at Calcutta at 44s. per ton, or about Rs. 80 per 100 maunds.—*Awbony on Salt Trade.*

But, according to another authority,—Calcutta Review,—Rs. 65 per 100 maunds is the lowest possible rate at which the transaction could be effected. But salt from the Persian Gulf and other Arab States is laid down at Calcutta at Rs. 40 per 100 maunds. It is therefore the high cost of producing Bengal salt (Rs. 80 per 100 maunds) which alone enables English salt to keep a footing in the Calcutta market.

In Bengal, salt is obtained by boiling the seawater.

In Bombay, and Madras, the process is that of solar evaporation.

In the Punjab, it is extracted in a pure state from the Salt Mines.

The Sambhur Salt Lake, in Rajpootana, overflows during the rains, and when the waters subside, a deep incrustation of salt is deposited on its shores for several miles round.

Salt purchased at Calcutta at 1d. per lb., the

## SALT.

Government price, is sold at Benares (400 miles from Calcutta, where it comes into competition with the salt from Rajpootana) at 12 lbs. the rupee, or 2d. per lb.; and, moreover, it is stated to be then considerably adulterated. The consumption of salt in India has been usually estimated [See.—Report of Board of Customs, Salt and Opium: Calcutta, 819 also Calcutta Review, 1847,] at 12 lbs. per head per annum; and assuming the wages of agricultural labour at three rupees per mensem (the rate now paid on the Calcutta and Bombay mail-road, and also to village watchmen), it would, at Calcutta, absorb the income of five days' labour to provide the quantity required for a year. The salt duty thus operates as a tax of about  $1\frac{1}{2}$  per cent. upon the labourer's wages, if he have none but himself to provide for. If he have a wife or children, the per centage will of course be increased by the amount of their consumption. It is to be observed, however, on the other side, that the wife and children would generally contribute something to the common fund by the earnings of their labour, and thus again reduce the per centage.

At Benares the purchase of the same quantity of salt (12 lbs.) would absorb ten days' earnings, thus constituting a charge of 3 per cent. on the labourer's income. But for this additional charge the Government duty is in no wise accountable. The difference in price is occasioned by the cost of conveyance, profits of trade, wastage, &c., the ordinary charges of commerce.—Of these the principal item is cost of carriage; but on the completion of the railway now in progress this will be greatly reduced in the district which it traverses. It is computed that the expense of conveying a ton of merchandise will not exceed  $2\frac{3}{4}$ d. per mile; consequently salt may be carried from Calcutta to Benares for one half penny per lb.

The pressure of the salt-tax on the labourer cannot be regarded as severe, inasmuch as it is the only way in which he contributes to the pecuniary necessities of the State; in all other respects he is not necessarily subject to taxation.

The preceding remarks apply to the Upper and Lower Provinces of Bengal. In the territories of Madras and Bombay the duty on salt is only about one-third of that which prevails in Bengal; but from other causes the mass of the people are believed to be in inferior circumstances to those of Bengal. In Madras they are still subject to various taxes (moturpha tax, duty on tobacco, &c.) which have been abolished elsewhere.

A comparison of the amount of salt produced with the numbers of the population consuming it, will show that the estimate which assigns 12 lbs. as the ordinary annual consumption of an individual, is nearly in correspondence with fact.

## SALT

The quantity of salt sold wholesale and retail or imported was, in 1846-47, as under:—

	Maunds of 82lb.
Bengal.....	6,166,258
N. W. Provinces.....	2,670,943
Madras.....	4,587,720
Bombay.....	2,573,625
	15,998,546
	82
	31,997,092
	127,988,368
	1,311,880,772 lbs.

If the entire population of *British* India be assumed at ninety nine millions, which from the latest official information may be considered as about its actual extent, the above-mentioned quantity of salt would afford to each individual about 13 lbs., the facts collected by statistical research thus corroborating an estimate founded on observation of the habits of the people.

The following table exhibits the quantity of salt imported into Calcutta from all countries, and also from England, for the last seven years. [Note.—Board of Customs, Salt, and Opium.]

	Imported from all countries.	From England.
	Maunds.	Maunds.
1844-45	970,595	791
1845-46	1,581,968	505,616
1846-47	1,466,744	352,835
1847-48	1,615,084	752,998
1848-49	1,626,706	459,808
1849-50	2,126,848	624,673
1850-51 (the first six months of)	1,455,007	672,092

Statement exhibiting the Net Revenue derived from Salt from all sources, viz., Government Sales, Excise on Private Manufacture, and Customs Duty, from the year 1839-40.

—HURKARU, May 30.

## SANATORIA OF INDIA.

(2713) SALTPETRE. The soil of the Belary district is very favourable for the manufacture of saltpetre. In the process, the earth is put into pits and mixed with saline water. The solution is afterwards drawn off into earthen pots, boiled, and afterwards poured into shallow vessels to crystallise.—*Cat. M. E. of 1857.*

### (2714) SALVINIA CUCULLATA.

A curious little floating plant, related to the ferns, of the genus salvinia is often seen on the surface of old tanks and stagnate waters in Tenasserim.—*Mason.*

### (2715) SAMANGKA.

The population according to the Districts is:—

	Men.	Boys.	Women.	Girls.	Total.
Samangka, . . . . .	2,337	3,736	2,507	3,426	12,006
Telok Betong, . . . . .	3,423	4,829	3,824	4,616	16,690
Sekampong, . . . . .	1,576	2,723	1,910	2,631	8,840
Marangie, . . . . .	326	544	421	509	1,800
Seputi, . . . . .	3,137	3,756	4,373	2,852	14,118
Tulong Bawang, . . . . .	5,132	9,145	7,976	7,197	29,450
Total, . . . . .	15,931	24,733	21,011	21,229	82,905

—*Jour. Ind. Arch.*

(2716) SAMBAH, amongst Malays, means obeisance, homage, &c., and is used for the ordinary word "to speak" by inferiors to a king; Salaam is the simple Arabic salutation, "peace," subjects or inferiors addressing a king are said to "Sambah" not to chakap or kata or other words used in common use.—*Jour. Ind. Arch. Vol. V. No. XI.*

### (2717) SANATORIA OF INDIA.

*Kussowlie*, is the station nearest to the plains, and is situated in Lat. 30° 56' North Long. 77° East, 45 miles distant from Umballah, and 32 from Simla, its height is about 6,400 feet, there is no table land, and the peaks are rather steep, and pretty densely clothed with fir trees: there is a plentiful supply of excellent spring water 700 feet below the barracks; the meat supplied to the troops is good, and latterly vegetables have been plentiful. The climate may be pronounced to be temperate and agreeable, unless during the rainy season, when dense fogs make it gloomy and depressing. The barracks during the early years of occupation were very inferior, having flat mud roofs, and rooms only 10 feet high, with clay flooring; lately, however, the rooms have been raised to 15½ feet, the floors have been boarded, and the roofs made to slope so that they do not leak.

*Subathoo* lies nine miles from Kussowlie on the road to Simla, at an elevation of only 4,000 feet; the hills are bare of wood, the climate differs from that of Kussowlie in being hotter in summer, and warmer in winter; it is altogether more dry and sheltered, and has an advantage in being seldom visited by fogs. The Barracks were at first unsuitable temporary buildings, but latterly

## SANATORIA OF INDIA.

they have been greatly improved and added to, and each man, both here and at Kussowlie is allowed space equal to 1,000 cubic feet of air, the water is good and abundant, and the supplies excellent;—the beef being varied occasionally by mutton.

*Dugshai*, is distant 18 miles from Kalka, and is 8 miles east of Kussowlie, and 10 miles south of Subathoo; its height ranges from 5,600 to 6,000 feet; the hills have a bleak and barren look, being completely bare of trees, and covered only by a long coarse grass. The situation, however, has the advantage of free exposure to the prevailing winds; water is abundant and good at the distance of a mile from the barracks which are new, substantial, and excellent, both in point of accommodation and ventilation. The rations are good and occasionally varied, and six acres of ground are laid out as a soldier's garden. The climate is said to be unexceptionable, although the heat of the summer is sometimes oppressive, and the cold of winter rather piercing. In 1851, August was the most rainy month, and in January there were two feet of snow on the ground.

*Simla*, the most in-lying station, is 77 miles from Umballah, in Lat. 30° 6' North Long 77° 11' East, the houses are scattered over an extent of about 7 miles, on a series of heights varying from 6,500 to 8,000 feet which is the highest elevation; it is in most places densely wooded with fir and Rhododendron, and there is much rank jungle which keeps the surface soil constantly damp; both here and at Kussowlie the heat of summer is somewhat tempered by the exhalations from, and the shelter of, so much rich foliage. The climate of the two stations is also very similar, and it has been compared with that of the Cape of Good Hope. The rains commence early in July, heavy dense clouds and fogs then load the air, and with this increase of humidity, disease becomes very prevalent. Water is scarce during the hot months, but I am not aware that it is bad, although many persons take the precaution to boil and filter it; supplies are abundant enough, but in general high-priced. Nothing can be worse than the state of conservancy, at least it was so up to the end of 1851. The smells along all the byepaths were most disgusting from accumulations of human ordure, offal, and dead animals in the numerous deep close ravines that intersect the station; in fact, a native population amounting to 10 or 12,000 persons was almost unrestrained by any police rules, and hence an amount of nuisance that is scarcely credible: the introduction of a Municipal Act has, I hope, greatly changed this state of matters. I can find no accurate data of the fall of rain at the several stations, it has been variously estimated at 60, 80 and 100 inches: at Kussowlie and Simla

## SANATORIA OF INDIA.

70 inches may be estimated as a fair annual average. The deep ravines and water courses, which intersect all the hills, are dry during the greater part of the year; the heated air ascends from these confined gorges, bringing in the rainy season dense clouds of mist, which are doubtless excellent media for the transmission of the miasmal exhalations that are generated in such places by moist warmth acting upon an abundant vegetation. The following table exhibits, as correctly as I have been able to ascertain, the mean temperature of each month:

STATIONS.	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	Height.	About 70 inches.	Fall of rain.
Kussowlie,.....	42°	47°	58°	64°	77°	73°	70°	70°	72°	66°	...	...	6400	...	...

Some of these figures are extracted from a communication by Colonel Sykes, read before the British Association for the Advancement of

## SANATORIA OF INDIA.

There are abundant statistical data of the prevalence of diarrhoea and dysentery at these stations, and the loss sustained has been so considerable as to lead to a very general belief that as sanatoria they have proved failures. In 1843-44, H. M.'s 9th Foot had 350 admissions from bowel complaint, and 57 deaths; while in 1844-45, its second year of residence, there were only 231 admissions, and 17 deaths. The 1st Bengal Fusiliers stationed at Subathoo in 1845, also suffered much, but both regiments came to the Hills in a very sickly state, the one having been decimated by fever and dysentery in Afghanistan, the other by a similar epidemic at Kurnaul during two years. The same may be said of H. M.'s 29th Foot, and the 2nd Bengal Fusiliers, the former having been in a sickly condition with a taint of scurvy for years before, and the latter having been very sickly in Scinde. In 1847-48, the 29th had 33 deaths out of 382 cases of diseases of the stomach and bowels, and out of 25 deaths in the 2nd Fusiliers, 13 were from this class of diseases.

Of late years, regiments in a less unhealthy state have been sent to the hills, and there has been very great improvement in the Barrack accommodation as well as in the conservancy department. In 1850-51, H. M.'s 60th Rifles were stationed, the right wing at Kussowlie, the left at Subathoo the average strength of the regiment was 1,002, and the deaths within the year only 14, of which however 13 were from bowel affections. At Kussowlie there were 220 cases, or 334 per cent. of average strength, with 9 deaths, and at Subathoo 74 admissions, or only 214 per cent., with 4 deaths, showing what has hitherto been rare in the history of these two stations, that the balance of salubrity was in favour of Subathoo. The admissions from diarrhoea were 221 with two deaths, but many more men were attacked, although not admitted into hospital. There were 82 admissions from chronic dysentery, of which 16 with 2 deaths occurred in the last quarter of the year, and chiefly in men who had suffered from repeated attacks of diarrhoea.

In 1851-52, the same regiment, with an average strength of 910 $\frac{2}{3}$ , had of total admissions 892; deaths 36, of which 27 were from bowel complaints, out of 252 admissions divided as follows; dysentery 35 cases and 9 deaths, diarrhoea 215 cases and 17 deaths against 221 cases with only 2 deaths in the previous year. On arrival at Jullunder there were in hospital 57 cases of bowel complaint, and out of the 36 deaths, 9 occurred there, but all from disease contracted in the hills. It will be observed that the actual admissions were less, but the mortality which in the first year had been only 1.39 per cent., to strength, rose to 3.95 per cent., the disease from repeated relapses or from concealment of it, becoming much more intractable.

In 1850-51, H. M.'s 22nd Regiment occupied

## SANATORIA OF INDIA.

Dugshai; average strength 1,049, deaths 27, of which 7 were from dysentery, and 1 from diarrhoea; the total admissions from this class of diseases were under 200, and the diarrhoea was peculiarly mild. In 1851-52 the second year of residence the average strength is stated to be 1,045 and the deaths at head quarters 20, of which 3 were from dysentery out of 47 admissions, nearly all preceded by frequent attacks of diarrhoea, and 3 from diarrhoea out of 199 admissions. During this year the regiment had fewer casualties, and fewer admissions into Hospital than in any year since its arrival in India. In 1851, during the cold season, it marched to Rawal Pindie, and for months after it had been there, it continued in a high state of health, and efficiency, and without any excess of bowel complaints among the admissions into Hospital.

Of the prevalence of diarrhoea at Simla there are no statistical data; but it has long been matter of notoriety. In slang phrase, the disease is called "Simla trots," and few persons escape one or more attacks in the course of the season. Of late years, however, it appears to have become much more general, and to have attracted more attention, in consequence of many visitors having neglected, or concealed the disease, and thereby experienced years of ill health. The attacks are not confined to persons in broken down health, who have suffered from periodic fever, or other tropical diseases; on the contrary, residents in the prime of life and of sound constitution, have been very generally affected, and among these, examples of its proving fatal are not rare; so late as last year two melancholy cases came under my notice. In one the diarrhoea was aggravated by the fatigue of a dawk journey, and proved fatal in Calcutta by terminating in malignant scorbutic dysentery; in the other, there was only the wasting painless form of disease, and death took place on the passage to England.

Of the various causes assigned, the first and most popular was the bad quality of the water: this however, has been disproved. The water from the springs on the North side of Kussowlie is very pure, while that on the South side is only impregnated with a trace of lime, but to a less degree than is found at many healthy stations in the plains. At Simla, in the hot season, the supply of water is scanty, and not of the best quality, but that is the time when diarrhoea is least common. During the rains the running streams are as pure as could be desired after the first few showers have washed out the water courses; besides, persons who were careful to use only boiled and filtered water did not escape the diarrhoea. Both at Simla and Kussowlie, the trees have gained the repute of producing the disease, by reason of their promoting damp exhalation, and preventing the free circulation of air. But Subathoo and Dugshai are bare of trees, and yet

experience no immunity from the prevailing *endemic*: shows In places the trees require thinning, in order to admit light and air, and to keep down the thick jungle which, at Simla especially, is, I believe, a source of noxious influence: it may be added that the results of experience are in favor of selecting sites, like that of Dugshai, clear of trees and jungle which promote humidity and afford materials for decomposition. The best founded and most influential exciting causes are the cold moist atmosphere, and the great and sudden vicissitudes of temperature by which perspiration is checked, leading to internal congestion, languid and impeded circulation in the liver and functional derangement of that organ. But these ungenial influences of temperature and moisture must have something superadded to them, to account satisfactorily for the inherent and peculiar liability of these localities to produce diarrhoea: the climate of Mussoorie is equally humid, but without the same tendency to diarrhoea, and this may be also said of Nainee Tal, Murree and Darjeeling, the last being remarkably cold and cloudy, and the air long supersaturated with moisture. Other mountain ranges also possess a similar immunity, such as the Neilgherries and Mahableshtar. There must, therefore, to account for its prevalence from year to year, be some cause other than the ordinary or essential climatic agencies, some limited morbid influence of a specific nature, and this appears to me to be partly malarious, partly scorbutic. We know that primary cases of intermittent fever are by no means uncommon at Simla and the neighbouring stations, and we meet with occasional cases of the worst form of typhoid remittent. In the season of 1850, at Simla, I witnessed two cases of malignant typhoid remittent fever; in one of these an officer on the general staff of the Army, the disease proved fatal; in the other, an A. D. C. on the staff of the Commander-in-Chief, recovery took place after a protracted and dangerous illness; both these officers must have contracted the fever at Simla, or in its immediate neighbourhood, probably in crossing some low foul ravine. But notwithstanding these proofs of malaria, experience teaches us that in general it is not here powerful enough to excite periodic fever: it seems to ascend from the numerous deep ravines and water-courses which intersect these stations, but to be so diluted, or changed by the effect of elevation, cold and moisture, as to cause bowel complaints instead, and this is exactly what occurs in some mountain ranges in other parts of the world, where we observe bad remittent fevers at the level of the sea. Intermittents at the higher level, bowel complaints higher still, and at the highest ulcers which appear as the feeblest result of malarious poisoning in depressing the vital powers. The cognate character of these diseases was also remarked in

China, and is noticed by Mr. Wilson in his "Medical Notes." In ships which lay at anchor at some distance from the shore, the miasma was received in a diluted form, and the seamen suffered from an inveterate species of ulcer obviously dependant on malarious taint in the blood.

I may notice also that an opinion has been gaining ground among medical officers in this Presidency that the epidemic ophthalmia, which has of late years been the source of so much inefficiency and loss in European regiments has its origin in the presence of a scorbutic diathesis among the men.—*Ind. Ann. Med. Sci. p. 312.*

(2718) SANDRACOTTUS. Chandragupta was an Indian prince of the time of Alexander and the Sandracottus of the Greeks. It was Chandragupta the Great who was a contemporary of Alexander. His grandson was the no less famous Asoka. The family name was Maurya. Chandragupta married a daughter of Seleucus.

The term Gupta is that of a race of Sovereigns who reigned in India, from the year A. D. 168 to A. D. 230, the first Chandragupta in 195 A. D. and the second A. D. 240.

(2719) SANSKRIT. The ancient Persian language east of the Euphrates was a near dialect of the Sanscrit. We are ignorant of the date of the introduction of the Arian branch of the Semitic tree into the regions South of the Hindoo Kush and its extension into the Sub Himalayan belt towards Hastinapur. For, as in the case of the Southern Alphabet, its earliest appearance within our ken, is in the counterpart edict of Asoka or Pyadasi, grandson of Chandragupta at Kapur de Giri in the Peshawur valley. And the greater amount of pure Sanscrit which the Kapur de Giri inscription carries in its text, illustrates the descending course of that language; and the ultimate and not very long delayed extinction of all trace of the once extensively prevalent Arian character, and its supercession by the more exact and appropriate system of writing, indigenous to the South. The chief Sanscrit authorities of the Buddhists, still in our possession, were written at the latest, from a century and a half before, to as much after, the era of Christianity. We may be satisfied therefore that the principal Sanscrit authorities which we still possess were composed by the beginning of the Christian era at least, how much earlier is less easily determined. The principal Pali authorities of the South are of a period considerably subse-

quent to the Sanscrit Buddhistical writings of India Proper and date only from the fifth century after Christ.

Professor Max Muller seems to concur in these deductions from his remarking that after Buddhism had been introduced into China, the first care of its teachers was to translate the sacred works from the Sanscrit, in which they were originally written, into Chinese, (*Buddhism and Buddhist Pilgrims*, p. 24. London. 1857) Colonel Sykes, however, still considers from his examination of Gutzlaff's Catalogue of Chinese Buddhistical works, that the books taken from India to China, by the Chinese travellers between the fourth and seventh centuries were equally in Pali. The great body of the Buddhist writings consists avowedly of translations. The Tibetan, Mongolian, Chinese, Cingalese, Burman and Siamese books, are all declaredly translations of works written in the language of India,—and that which is commonly called Fan or more correctly Fan-lan-mo—or the language of the Brahmans. This was in India Proper, undeniably the Sanscrit language, though the Buddhist authorities of Ceylon may have been Pali. The Sanscrit works as they have come into our hands, have been found almost exclusively in Nepaul; those in Pali being obtained chiefly in Nepaul and Ava. Pali is the language of the Buddhists of Ava, Siam and Ceylon; therefore it is concluded it was the language of the Buddhists of Upper India, when the inscriptions on the Lats were engraved; and consequently that they are of Buddhist origin. This however is questioned; it being asserted that the doctrines of Buddha were long taught orally only, and were not committed to writing for four centuries after his death, or until B. C. 153, a date no doubt subsequent to that of the inscriptions. Buddha died 543 years before Christ.

According to Mr. Burnouf and Mr. Hodgson, the earliest Buddhist writings were not Pali but Sanscrit, and they were translated by the Northern Buddhists, into their own languages, Mongol and Tibetan. The Buddhist authorities assert that Sakya Sinha and his successors taught in Pali, and that a Pali grammar was completed in his day. It is not likely that the edicts of Asoka, intended to regulate the moral conduct of the people at large should have been intelligible only to Buddhist priests, or should have been perpetuated only on pillars for their edification. We may therefore recognise it as an actually existent form of speech in some part of India, and might admit the testimony of its origin given by the Buddhist themselves, by whom it is always identified with the language of Magadha or Behar, the scene of Sakya Sinha's first teaching—but that there are several differences between it and the Magadhi, as laid down in Prakrit grammars, and as it occurs in Jain writings. It seems therefore to have been a form of speech

peculiar to the people of Upper India. Of Pali alphabets, may be mentioned that of the Girnar Rocks. The Asoka alphabet (the Sanscrit one.) Tibetan is acknowledged to be of the seventh century. And the Kuteli alphabet of Bareilly.

The ancient Pali or Maghadi alphabet had once a very extended currency, and for a lengthened period retained its separate identity. It occurs in Asoka's edicts at Delhi, Allahabad, Matia, Bakra, Dhauli and Girnar: its appearance in these several localities, would *prima facie* imply that it was intelligible to the people at large, throughout the circle embraced by these geographical boundaries, or that it was the recognised sacred alphabet of Buddhism. Opposed to the latter supposition is the departure from its use in the Kapur-di-giri text of the edict itself and the modification the language is seen to have been subjected to, in some of the Pali transcripts, to meet apparently the local dialects of each site. The available medallie testimonies of coins contributes largely to the inference that these characters formed the ordinary medium of record in the majority of the states included within the limits above alluded to. In this alphabet exclusively are expressed the legends of innumerable series of coins of purely local type; its characters are found associated on the one part with the Greek of Agathocles and Pantaleon and its phonetic signs are conjoined with counterpart Arian legends on certain classes of the Behat coins. Dr. Stevenson remarks, in speaking of the Nasik cave inscriptions, that on the whole, we find that Brahmans and Buddhists, in these early days of our era, lived in peace with one another, and were both favoured and protected by the reigning sovereigns, and that among the former, the Sanskrit language was used in writing and the Prakrit by the latter, the two languages probably holding the same place to one another that the Sanscrit and the Vernaculars do at present.—*Jour. Bomb. Ro. As. S.* 1st July, 1853, p. 41.

Mr. Caldwell says that the Dravidian languages are to be affiliated not with the Indo-European but with the Scythian group of tongues and the Scythian family to which they appear to be most allied is the Finnish or Ugrian. The idioms which he includes under the general term Dravidian constitute the vernacular speech of the great majority of the inhabitants of Southern India. With the exception of Orissa and those districts of Western India, and the Dekhan, in which the Guzerathi and the Marathi are spoken, the whole of the peninsular portion of India, from the Vindhya mountains and the river Nerbudda, (Narmadâ) to Cape Comorin, is peopled, and from the earliest period appears to have been peopled, by different branches of one and the same race, speaking different dialects of one and the same language, the language to which the term Dravidian is here applied, and

cattered off-shoots from the same stem may be traced still further north as far as the Rajnahal Hills, and even as far as the mountain fastnesses of Beluchistan. The Guzerathi, the Marathi, (with its off-shoot the Konkani) and the Uriya, or the language of Orissa, idioms which are derived in the main from the decomposition of the Sanskrit, the vernacular speech of the Hindu population within these respective limits: besides which, and besides the Dravidian languages, various idioms which cannot be termed indigenous or vernacular are spoken or occasionally used by particular classes resident in Peninsular India. The idioms which Mr. Caldwell designates as "Dravidian" are nine in number, exclusive of the Rajnahal Uraon and the Brahui: They are as follows,

1 Tamil,	4 Malayalam,	7 Kota
2 Telugu,	5 Tulu,	8 Gond or Goond,
3 Canarese,	6 Toda or Tudara,	9 Khund or Kund, or Ku

The last four languages are entirely uncultivated. The proportionable numbers of the several races by whom the languages and dialects mentioned above are spoken appear to be as follows

1 Tamil spoken by	...	10,000,000
2 Telugu	...	14,000,000
3 Canarese	...	5,000,000
4 Malayalam	...	2,500,000
5 Tulu	...	150,000
6 to 9 Toda, Kuta, Gond and Khund		500,000

---

32,150,000

Whilst he regards the grammatical structure and prevailing characteristics of the Dravidian idioms as Scythian, he claims for them a position in the Scythian group independent of its other members, as a distinct family or genus, or at least, as a distinct subgenus of tongues. They belong not to the Turkish family, or to the Ugrian, or to the Mongolian or to the Tungusian,—but to the group or class in which all these families are comprised. On the whole the Dravidian languages may be regarded as most nearly allied to the Finnish or Ugrian family, with special affinities, as it appears, to the Ostiak.

The conclusions arrived at by Mr. Caldwell with regard to the Northern languages are summed up thus—

It is admitted that before the arrival of the Aryans, or Sanskrit speaking colony of Brahmans, Kshatriyas, and Vaisyas, the greater part of Northern India was peopled by rude aboriginal tribes, called by Sanskrit writers Mlechhas, Dayas, Nishadas, &c., and it is the received opinion that those aboriginal tribes were of Scythian or, at least, of non Aryan origin. On the irruption of the Aryans, it would naturally happen that the copious and expressive Sanskrit of the conquering race would almost overwhelm the vocabulary of the rude Scythian tongue, which was spoken by the aboriginal tribes. Nevertheless, as the grammatical structure of the Scy-

thian tongues possesses peculiar stability and persistency; and as the pre-Aryan tribes, who were probably more numerous than the Aryans, were not annihilated, but only reduced to a dependent position and eventually in most instances incorporated, in the Aryan community, the large Sanscrit addition which the Scythian vernaculars received, would not necessarily alter their essential structure or deprive them of the power of influencing and assimilating the speech of the conquering race. According to this theory, the grammatical structure of the spoken idioms of Northern India, was from the first, and always continued to be, in the main Scythian. And the change which took place when Sanscrit acquired the predominance, as the Aryans gradually extended their conquests and their colonies, was rather a change of vocabulary than of grammar,—a change not so much in the arrangement and vital spirit of Dravida as in the material of the language. This hypothesis seems to have the merit of according better than any other with existing phenomena. Seeing that the Northern vernaculars possess with the words of the Sanscrit, a grammatical structure which in the main appears to be Scythian, it seems more correct to represent those languages as having a Scythian basis, with a large and most overwhelming Sanscrit addition than as having a Sanscrit basis with a small admixture of a Scythian element (page 38). The Scythian substratum of the North-India idioms presents a greater number of points of agreement with the Oriental Turkish or with that Scythian tongue or family of tongues of which the new Persian has been modified, than with any of the Dravidian languages.

The locality of the Andhra dominion has hitherto been as uncertain as the period of its sway. Wilford says at one place that the Andhra princes made a most conspicuous figure on the banks of the Ganges for above 800 years. Again, that Andhra and Koshala (near Kalinga) are used synonymously by some Hindu authors: again, that Sricarna-deva took the title of king of Tri-Kalinga, or of the three shores, to the east and west and south of India. The general term of Dakshinapetha (Dekhan) agrees well with the latter definition, and we may rest content with denoting the Sata Karnis as Kings of the Peninsula. There were Andhras at the beginning of the Christian era, when, says Pliny, the Andaræ Kings were very powerful in India, having no less than thirty fortified cities, an army of 100,000 men and 1000 elephants.—*Prin. Ind. Ant. Vol. II. p. p. 31, 33; 34; 45; 46; 50; 51 and 67.*

(2720) SAPI, name given on the Moar river to a wild cattle, with much the appearance of Bali cattle, but without the white patch on the buttocks. The horns are small, curved in-

wards, white, tipped with black, the forehead is flat, with a tuft of long hair on it, particularly on the bulls.

(2721) SAPOTA ELENGOIDES, a large tree common on the Neilgherries, wood strong and elastic like the hawthorn, burns well when green, —*McIvor, M. E.*

(2722) SARCOCOCCA TRINERVA OR NEILGHERRY BOX WOOD. Tree very common on the Neilgherries, wood hard and durable, might be used as common Box wood in the arts. —*McIvor, M. E.*

(2723) SARHI. HIND. MAR. PUDAWI, TAM. A garment worn by women in India. Viscountess Falkland, in Chow-chow page 7, says, I saw a group of women, with their heavy anklets, 'making a tinkling with their feet, (Isaiah iii. and 16,) their sarhis folded over their heads and persons, and carrying little chubby children on their shoulders, or astride on their hips; and now these are lost to sight, and a fresh group appears, consisting of Hindoo women of various castes, clothed in jackets and sarhis of divers colours, and wearing the 'chains and the bracelets' the earing, 'the rings and the nose rings.' Isaiah iii, 19 and 21."

The Sarhi is the name of the mantle or veil worn by the women of India, one end forms a very voluminous kind of skirt or petticoat, the other end is then drawn over the head and shoulders, somewhat in the style or form of a Maltese faldetta. —*Viscountess Falkland Chow Chow, page 7. London 1857.*

(2724) SASSANIAN MONARCHY. This commenced, in Persia, in the year 223 A.D. when Artaxerxes overthrew the Parthian dynasty, and it continued until itself overturned by the Mahomedan Khalifs in the year A.D. 636. —*Prin. Ind. Ant. p. 13.*

(2725) SATRAP: KSIATRAPAS. Sans. Although wholly unknown as a sovereign title to modern Hindus and not to be found in their books, this term is familiar to the reader of the Grecian history of ancient Persia, with merely a softening of the initial letter, as Satrapa ΣΑΤΡΑΠΗΣ, the prefect of a province under the Persian system of Government. It is an obsolete Persian title (Hind.) for the governor of a province. In Sanscrit it signifies the ruler, feeder, or patron of the Kshatra or military class, and now that we know the ancient language of Persia east of the Euphrates to have been a new dialect of the Sanscrit, we may conclude that Satrapa had the same signification in Arabia. The effeminate Persians, at a very early period were in the habit of governing their numerous tributary provinces by mercenary troops. The same system and the same denomination of Satrap, was adopted and retained by the Macedonian conquerors, alike when Greek or native

officers were employed. And instances are frequent enough of the Satraps assuming to themselves independence and a regal title. The Satrapies of the ancient Persian monarchy are not supposed to have extended across the Indus. It was in Alexander's time this limit was first transgressed, it was not long prior to the time when the Bactrian Greeks or the Parthians, made themselves masters of Sindh, Kutch and Gujarat —*Prin. Ind. Ant. Vol. II. p. 64.*

(2726) SATPURA MOUNTAINS. On a spur of this range near the Nerbuddah is a Colossal Jain figure cut in relief nearly 80 feet high.

(2727) SATR-SOWA. Myrtus communis. Myrtle leaves are eaten with black pepper to cure emissions that occur from debility. —*Genl. Med. Top. p. 152.*

(2728) SAYUR KALADI. Malay. Sayur is the generic term for vegetables. Kaladi is a species of vegetable (the Arum colocasia of Roxburgh) with a large leaf and an edible root, which grows in marshy ground and is much used by the Chinese for food for their pigs. —*Jour. Ind. Arch. No. XI. Vol. V.*

(2729) SEENKH. HIND. The Culm of the Khuskus. Andropogon muricatus.

(2730) SEHARUNPORE, in North-Western India, the site of the Botanical Gardens of the Government of India.

(2731) SEIDBURROO. A Nepaul tree, the bark of which is manufactured into a strong useful paper; it is also made into rope and black thread, but neither of them resist moisture well. —*Smith's Nepaul.*

(2732) SERAPADA OR SRIPADA, the name given in Ceylon to the footstep of Buddha, on the mountain Sumanakuta or Adam's peak. —*India in the 15th Century.*

(2733) SEVALIK HILLS, A Sub Himalayan range, chiefly known to science for the numerous fossil remains discovered in them. Fossil Camels, a fossil Gharial: fossil bear (ursus sivalensis); fossil tiger (felis cristata): a new fossil ruminant called Sivatherium giganteum and many others, mammals and reptiles.

(2734) SEVATHERIUM GIGANTEUM. A fossil ruminant discovered by Sir P. T. Cautley in the Sewalik Hills.

(2735) SHADEE. See NIKAH.

(2736) SHAN. The Shans, or Tai as they call themselves, are the most extensively diffused and probably the most numerous of the Indo-Chinese races. Lapping the Burmese round, from North-west by north and east to South-west, they are found from the borders of Munnipoor to the heart of Yunan and from the valley of Assam to Bangkok and Kamboja; every where Buddhist; every where to some extent civilised,

and every where speaking the same language with little variation. Their traditions as also those of Siam, speak of a great kingdom held by this race in the north of the present Burmese Empire, but the race is now split into a great number of unconnected principalities and the kingdom of Siam is now perhaps the only independent Shan state in existence. All the others are subject or tributary to Ava, China, Cochin China or Siam.—*Yule, Jour. Roy. Geog. Soc. Vol. xxvii. 1857.*

(2737) SHENDOOS. See HEUMA.

(2738) SHIM is the Tamil and Malayala name of a tree commonly known as the "Buttress tree." It grows to an enormous size. Edye saw one forty-five feet in circumference, and one hundred and ten feet long. It is a soft, spongy sort of wood of a white colour; not durable, or of much use, unless it is oiled, when it may last for five or six years for canoes or catamarans, provided they are taken out of the water when not wanted. If it be kept in water, two years will render it water-logged and useless.—*Edye. M. & C.*

(2739) SHOU. *The shou or Tibetan stag, Cervis affinis*, [Note. Dr. Campbell, superintendent of Darjeeling has presented to the Society the horns and skin a very fine specimen in beautiful preservation.]

The Shou is from eight and a half to nine feet in length and from four and a half to five feet high at the shoulder. The head is twenty-two inches long, nine deep and seven and three quarters wide. The ears are eleven inches long. The tail, less the hair, is three to four inches. The fore leg, from mid flexure downwards, is eighteen inches; and the hind leg, nineteen inches and more. The fore hoof is four and half inches long, three and three-eighths wide, and three high. The hind hoof, four and one quarter inches long, three in width and the same in height or depth. The horns are five feet long, three to four in spread between the tips, and ten to eleven inches thick at base.

The general form of the animal is full of grace and vigour; assimilated to that of the European stag, but with greater strength of limbs and broader hoofs. The head is finely shaped with broad flat forehead a little depressed before the horns, a slightly arched chaffron and graceful termination forwards, not actually thickened, as I had supposed, though less attenuated, than in Hippelaphus, Elaphoides and Axis, or the tropical Deer; and the muzzle or rude extremity of the nose is decidedly smaller than in them, perhaps even more so than in the stag of Europe. The suborbital sinus is likewise conspicuously smaller, in skin and in skull, than in the tropical Deer just cited, or in the Muntjacs, though not inferior in size to the same organ in our red deer, I apprehend. In the feet there are no interdigital pores, before or behind; nor

are there apparently any calcic tufts or glands; though in one sample a rudity appears on the os calcis which has somewhat the semblance of this latter organ.

The graceful and majestic horns are inserted on the summit of the frontals but much before the occipital crest, upon a moderate foot-stalk which reclines considerably and is surmounted by a moderate-sized burr. The horns have an ample sweep and curve, both spreading and reclining much, and then approximating more or less, and for the most part greatly so, towards their tips, thus forming large segments of circles.

Mr. Hodgson has no longer any doubt that the Shou is the same species as that described by him under the name of Affinis in the journal, ten years back, I got, he says, that splendid sample in the Tarai; but it had, I now conclude, been carried there from the Himalaya or from Tibet. The Shou inhabits a wide extent of country in Tibet, but is rarely if ever found in Chumbi, and not at all in the juxtanivean districts of Bhutan, as priorly affirmed. Wherefore it cannot be classed as Himalayan as well as Tibetan. Capt. Cunningham assures me that the stag of Cashmir is the same animal; but Mr. Gray and Dr. Falconer judge otherwise; and, as it now appears that the Shou is *not* found in any cis-Himalayan district, nor even in Chumbi with its half Himalayan and half Tibetan climate, I think this identity very questionable, as also that with the Maral or stag of Persia. But I am strongly inclined to the conjecture that the stags of Mongolia, of Manchuria, and of southern Siberia, are all identical in species with the Shou; and I am almost satisfied that the Stag of Tibet is specifically the same with the Wapiti of North America, especially that of Canada or the Canadian variety, called often the North-western stag. Besides the ample spoils of the Shou, I have now before me a stag's horn from Ladak which may possibly belong to this species, though, being that of a young animal, I cannot say. It is anomalous if appertaining to the Shou by the extreme remoteness from each other of the two basal lines, which in a horn of but 34 inches long is above 4 inches ( $4\frac{1}{4}$ ), whilst the next snag above may be the central, or it may be the apical, one.

(2740) SHUB-I-BURAT. PERS. This Mahomedan feast is held on the 14th and its *arfa* on the 13th of the eighth month Shaban.

(2741) SHUB-GUSHT. PERS. Nocturnal perambulation, a ceremony practiced by the Mahomedans in India, on occasions of marriages; circumcision, &c.—*Herz.*

(2742) SHUJH OR MILK TREE. Grows to an enormous size on the summit of the lofty Hills north of Nepaul.—*Smith's Nepaul.*

(2743) SHUREEF. ARAB. The progeny of

## SILVER COINAGE OF INDIA.

a-Sheikh father and a Syedani, amongst Mahomedans.

(2744) SHUWAL, ARAB. The tenth month of the Mahomedan year.

(2745) SHIVE-DAGON. This has for two thousand years "shot upwards, like a pyramid of fire" athwart the dismal flats of the delta of Pegu. The height above the ground level is 487 feet and above the platform 321 feet.

(2746) SHIVE-OO-DOUNG. A great mass of mountains which runs parallel to the Irawaddi as far as Amarapura, one peak estimated to be 6000 feet in height.

(2747) SIRI. The ancient name of the ancient city of Delhi; prior to its capture in A. H. 587, A. D. 1191.—*Prin. Ind. Ant.* 326.

(2748) SINDBAD. A voyager, well known to Europe as having his history incorporated in the Thousand and one nights, but they form in Arabic a distinct and separate work, which Baron Walkenaer (in *Nouvelles Annales des Voyages*, tom. liii p. 6) regards of equal value with those of Soliman and Abu Said. His first voyage appears to have been to the Western Coast of India when the Bejanuggur dynasty ruled, as he calls it Maharaj. Riha, was the termination of his second voyage, and was probably the Malay Peninsula as he describes it as producing camphor. And in his third voyage the island with ferocious savages seems to have been the Andaman. His fourth voyage would seem to have been the coast of Malabar, whence he went to the island of Nacaus apparently the Nicobars, thence in six days to the island of Kela, which Baron Walkenaer recognises as Quedah in the Malay Peninsula. In his fifth voyage where he is shipwrecked and becomes the victim of the Old man of the sea, the site is supposed again to be the Malabar Coast. After his escape he visited the Maldives, Cape Comorin, for Aloes wood, and to the Gulf of Manar for Pearls. In his sixth voyage, he is thrown on an island where superb Aloe wood trees, *Santy* and *Comari*, were growing, whence he finds his way to Serendib the present Ceylon, which was the object of his seventh and last voyage where he was sent as ambassador from Caliph Haroon oor Rasheed.—*Ind. in the 15 Cent.*

(2749) SIN-HOA, Aurea Chersonesus.

(2750) SILVER COINAGE OF INDIA.

Silver is the legally constituted medium of exchange in all money transactions throughout the British Indian possessions.

Gold coin was till lately a legal tender, at a fixed value of sixteen rupees for the Gold Mohur of Calcutta, and fifteen Rupees for that of Madras and Bombay: but it was not demandable in payment and was left to find its current value in the market.

## SILVER COINAGE OF INDIA

By a notification of the Government of India on the 22nd December 1852, it was declared that on and after the 1st of January 1853, no gold coin should be received on account of payments due, or in any way to be made to the British Government of India. The motive and object of the order was to escape from the consequences of the condition of the gold coin of India, and the erroneous principles, adopted for its manufacture, at a time when the gold of California and Australia, began to affect the market. The first considerable increase in the import of gold at Calcutta was in the year 1848-1849, and a large portion of it was sent to the mint, in that and the following years, for conversion into the low standard lion-device pieces, brought out by Act XVII of 1835. The sending of gold to the mint at this period, was in reality, a mere sale of the metal to Government for silver, at the par rate of 15 to 1, which then began to prevail as the market rate. The Mint certificates, obtained for gold delivered were immediately paid in at that par, in satisfaction of Government dues, or were negotiated at the banks, where silver was always claimed upon them under the option then given of receiving the amount in rupees at the par in question. And thus the gold which had been coined at the Mint remained as a dead balance in the Government Treasury, owing to its not being issuable at the par of 15 to 1, in the condition of base standard coin to which it had been manufactured. Besides the accumulation produced through gold deliveries at the Mint of Calcutta, low standard coin, previously issued, began also to be paid into the Treasury, at the established par rate in ordinary transactions, under the Proclamation of 1841, so that out of a total amount of lion-device gold mohurs, not exceeding in value seventy lacs of rupees, which was the value of the coinage up to that date, more than fifty lacs were, in 1852, in deposit in the Government Treasury, as a dead unserviceable balance.—*Vol. II. p. 70.*

In the eight years 1846-47 to 1853-54 the total quantities of Silver Bullion minted at the three Presidencies, was

For the year.	Cos. Rupees.	For the year.	Cos. Rupees.

The rupee is the unit or standard measure of value throughout India, and by the Regulation, a perfect assimilation in weight and fineness has been effected in this unit of currency of the three Presidencies, so that the rupee of Upper India, of Madras, and Bombay are now identical in value. The great variety of coinage which formerly existed, the Arcot or Madras Rupee, the Furruckhabad Rupee, the Bombay Rupee, the Moorsheadabad or Sicca Rupee, has thus ceased, and it is only in Native states, with independence, that other local coins are current.

The following table exhibits the scheme of the British Indian monetary system :

Gold muhr.	Rupee.	Anna.	Paisa.	Pai.
Calcutta..... 1 ...	16	256	1024	3072
Madras & Bombay 1 ...	15	240	960	2880

	...	1	4	12
	...	...	1	3

Copper coin is only a legal tender at the established rate of sixty four paisa to the rupee, on payments falling short of a rupee.

Small shells called Cowries or Kauris كوري are also made use of for fractional payments and are reckoned as follows :

- 4 Kauris make 1 Ganda.
- 20 Gandas ,, 1 Pan.
- 5 Pans ,, 1 Anna.

but their value is subject to considerable fluctuation.

Silver pieces, of eight annas, four annas, and two annas, are struck of equal proportionate weight with the rupee: and copper coins of half anna, quarter anna, and one-twelfth anna complete the coined currency.

The numerous Mints, the great debasement of their coinage and the complications resulting therefrom, led the Government of India, on the

## SILVER COINAGE OF INDIA.

10th September 1824, to resolve on the abolition of several Mints and to induce Native Sovereigns to equalise their rupees with those of other Mints. At that time, none of the coins forming the circulation of Hindustan, bore any other name than that of Shah Alum.

All the British Mints in India are open to the reception of gold and silver bullion for coinage on private account, and the following is the course of proceeding in the Calcutta Mint. After examination by the processes of cutting and burning, to ascertain that there is no fraudulent admixture, the proprietor takes a receipt from the Mint Master, for the weight of his bullion. A specimen is then taken from Assay, and after that operation the Mint receipt is exchanged at the Assay Office, for a Certificate of the Standard value of the bullion in gold or silver money. This Certificate is convertible into cash at the Treasury as soon as the new coin may be transmitted thither from the Mint.

A deduction is made from the Assay produce of bullion, to cover the expenses of coinage, which vary at the different Mints as follows :

	On Gold Bullion.	On Silver Bullion.
At the Calcutta Mint	2 per cent.	2 per cent.
"    Madras	3 "    "	2 "    "
"    Bombay	2½ "    "	2 "    "

On the re-coinage of rupees struck at the Mints of the Bengal Presidency, a charge of 1 per cent only is levied.

The following notes on the names of the coins and the schemes of the coinage of Eastern and Southern Asia may be found of interest.

(2751) *Ashrapi*. Moorshedabad Gold Mohr, has a weight of 190·895 grains troy.

(2752) *Adhela*, from adha, Hind, half signifies the half of a paisa.

(2753) *Ava specie*. The Burmese, it is well known, have no coined money, but, like the Chinese, make their payments in the precious metals by weight. Like the latter nation, also, they make use of decimal divisions in estimating the value or purity of gold and silver, and their systems of weight and measure follow the same convenient scale. Major Burney, Resident at Ava, gave the following particulars :

Vis, Tikal, and Moo are the general terms used in the transactions of commerce and accounts : their subdivisions and multiples are,

- 1 pe or be.
- 2 = 1 moo.
- 2½ = 1 mat.
- 5 = 2 = 1 hkwe.
- 10 = 4 = 2 = 1 kyat or tikal.
- 1000 = 400 = 200 = 100 = 1 peiktha or visson.

100 tikals are precisely equal to 140 tolas.

The expressions employed by the Burmese goldsmiths in declaring the quality of bullion

## SILVER COINAGE OF INDIA.

require a knowledge of the Burmese numerals, and a few other words :

NUMERALS.		METALS.	ASSAY TERMS.
1. Ta.	6. Khyouk.	Shew, gold.	Det, better or above.
2. Nheet.	7. Khwon.	Shwence, Red or pure gold.	Mee, differing + or —.
3. Thoun.	8. Sheet.	Nguee, silver.	Meedet, better in assay.
4. Le.	9. Ko.	Ge or khle, lead or alloy.	Meeshyouk, worse ditto.
5. Nga.	10. Tshay.	Nee, copper. Byoo tin.	Ma, adulterated.

The usual weight of the small lumps of silver current in the place of coin is from twenty to thirty tikals (thirty or forty tolas) : they bear a variety of names from their quality and appearance, the figures given by the action of the fire upon a thick brown coating of glaze (of the oxydes of lead and antimony) answering, in some degree, the purpose of a dye impression.

'*Ban*' signifies 'pure' or 'touch,' and is the purest obtainable of the Burmese process of refining. The word *Ban* is synonymous with the 'Bani' of the 'Ayin-i-Akbari.' *Banwari* is the Indian name of the touch needles used in roughly valuing the precious metals.

*Kharoobat*, 'shelly' or 'spiral circled,' is applied to a silver cake, with marks upon its surface, produced by the crystallization of the lead scoria in the process of refinement: it is supposed to denote a particular fineness, which, by Burmese law, ought to be ten-ninths yowetnee in value, i. e., nine tikals of *kharoobat* pass for ten of yowetnee silver; or it should contain nineteen and a quarter *ban* and three quarter copper.

*Yowetnee*, red-leaved flowers or star, silver, is so named from the starry appearance of the melted litharge on its surface. *Yowet* is a corruption of *rowek*, 'leaf,' and the word is sometimes written by Europeans *rowanee*, *rouni*, *roughanee*, etc. *Yowetnee* is the Government standard of Ava, and contains by law eighty-five *ban* and fifteen alloy per cent. Taking it at nine-tenths of purity of *kharoobat*, which last is 94.6 touch, its quality will be 85.2 fine; which closely accord with the legal value. The average of 60,000 tolas of yowetnee in the late Ava remittance turned out two dwts. worse (90.8) but there was a loss of more than one per cent, in melting, from the exterior scoria.

*Dain*, the most common form of bullion met with in circulation, is so called from an assessment, levied during the late king's reign, upon villages and horses: *dain* signifying 'a stage,' or distance of two miles. These cakes also weigh from twenty to thirty tikals each. Their prescribed legal quality is ten per cent. better than yowetnee, which puts this species of silver on a par with *kharoobat*. In practice, however, the quality varies from one to ten per cent. better (five Br. to thirteen and a half Wo.) than Calcutta standard. The average of fifty-two lakhs of *dain* turned out three penny-weights

## SILVER COINAGE OF INDIA.

There is an adulterated *dain* silver, stated by Major Burney to be similar in quality to yowetnee, but in reality much worse (forty-two and a half pennyweights worse) lately introduced and extensively circulated: it is made by admixture of lead, and is called *Ma-dain*.

The following will serve as examples of the mode of valuating bullion :

*Dain*, *ko-moo-det*, is *Dain* nine per cent. better. (See previous explanation.) *nga-moodet*, five per cent. better. *Yowetnee*, standard, (Eighty-five touch.)

*Kyat-ge*, or *ta-tshay-ge*, one tical or tenth of alloy (meaning one-tenth weight of alloy added to standard).

*Kyouk-tshay nga-kyat-ge*, six tens five tical alloy (meaning sixty-per cent. of alloy added). *gyan*, half yowetnee (and half alloy.)

*Gold*. The purity of gold is expressed by moss or 'tenths' only; ten moss, 'tshay moo,' (one hundred touch) being esteemed pure gold.

'*King's gold*,' or standard, is called *Ka-moo-ta pe-le-yowe* (nine moss, one pe, four seeds), or nine and three-quarter moss fine.

'*Merchant's gold*' is *Ko-moo-ta-be*, nine and a half moss fine. Gold muhrs are called eight and a half moss fine by the Ava assayers.

(2754) *Bactria*. In the reign of Antiochus II, the third of the Selencidæ, Theodotus, the Governor of Bactria, revolted and established an independent monarchy, his capital was the modern Balkh, and his extensive kingdom included parts of Cabul, Khorasan and Bokhara, by aid of their coins, the names of nine of their princes have been brought down to us. Coins have been discovered at Surapura and Mathura, between Agra and Etawah, and others in the Punjab.

Indeed both Grecian and Persian coins are met with frequently in India. General Ventura and Sir Alexander Burres collected many Greek coins in Ancient Bactria and the Punjab. Major Tod discovered one of Apollodotus and one of Menandu at Mathura. From the coins, there is reason to believe that the Greek princes were succeeded by Buddhist rulers.

(2755) *Cash*, کاش Hind. A small coin once current in Southern India. Twenty cash being equal in value to four falous.

*Kas* may be a corruption of the Sanscrit word *Karsha*: which is mentioned in Colebrooke's Essay on Indian Weights, as the same with the word *pan*. A *Karsha*, or eighty raktikas (ratis) of copper is called a *Pana* or *Karsha-pana*. It is now the eightieth part of a *pan*, but similar discrepancies are common throughout, and the simple word is all that can be identified as having survived the changes of system.

According to the old Madras system, accounts

## SILVER COINAGE OF INDIA.

8 kas = 1 fanam

336 „ = 42 (silver) fanams = 1 Pagoda

The Company reckoned twelve fanams to the Rupee and three and a half Rupees to the pagoda. But the bazar exchange fluctuated between thirty-five and forty-five silver fanams per pagoda: fanams were also coined in a base gold.

Copper 1, 5, 10, and 20 kas pieces were coined in England, by contract, for Madras, so early as 1797. The 20 kas, was also called “dodo” and falus. The Star Pagoda weighs 52.56 grains and is nineteen one-fifth carats fine. It is therefore, intrinsically worth 7 shillings  $5\frac{1}{4}$  sterling, but it is commonly valued at 8 shillings. Many varieties of the Pagoda used to circulate on the Coromandel coast, but since 1833 they have been only obtainable when sought for.

In 1811, a coinage from Spanish dollars took place, consisting of double rupees, rupees, halves and quarters; and pieces one, two, three and five fanams, the rupee weighed 186.7 grains. A silver coinage of half and quarter pagodas, of dollar fineness, also then took place; the half pagoda weighed 326.73 grains troy, and was equal to  $1\frac{1}{4}$  Arcot Rupees. By a proclamation of 7th January, 1818, the silver rupee of one hundred and eighty grains, was constituted the standard coin, and all accounts and public engagements were ordered to be converted at the exchange of three hundred and fifty rupees per hundred pagodas. The proportion between the old and new currency then became  $3\frac{1}{2}$  rupees per pagoda, and in copper (75) seventy-five kas old currency = 14 paisa new currency.

(2756) *Chinese Currency.* Sycee silver, in Chinese Wan yin, is the only approach to a silver currency among the Chinese. In it, the Government taxes and duties, and the salaries of officers, are paid; and it is also current among merchants in general. The term Sycee is derived from two Chinese words, Se-sze, ‘fine floss silk,’ which expression is synonymous with the signification of the term Wan. This silver is formed into ingots, (by the Chinese called ‘shoes’) and by the natives of India, khuri, or ‘hoofs,’ which are stamped with the mark of the office that issues them, and the date of their issue. The ingots are of various weights, but most commonly of ten taels each.

Sycee silver is divided into several classes, according to its fineness and freedom from alloy: the kinds most current at Canton are the five following:—

(a) *Kwan-heang*, ‘the Hoppo’s duties’, or the silver which is forwarded to the imperial treasury at Peking. This is ninety-seven to ninety-nine touch. On all the imperial duties, a certain percentage is levied for the purpose of turning them into Sycee of this high standard, and of conveying them to Peking without any loss in the full amount. The Hoppo, however, in all probability increases the per-centage far above what is re-

## SILVER COINAGE OF INDIA.

quisite, that he may be enabled to retain the remainder for himself and his dependants.

(b) *Fan-koo or Fan-foo*, the treasurer’s receipts, or that in which the land-tax is paid. This is also of a high standard, but inferior to that of the Hoppo’s duties, and being intended for use in the province, not for conveyance to Peking, no per-centage is levied on the taxes for it.

(c) *Yuenpaou or Une-po*, literally ‘chief in value.’ This kind is usually imported from Soochow, in large pieces of 50 taels each. It does not appear to belong to any particular government tax.

(d) *Yen or Eem-heang*, ‘salt duties.’ It is difficult to account for these being of so low a standard, the salt trade being entirely a government monopoly. This class is superior only to

(e) *Mut-tae or Wuh-tae*, the name of which, signifying ‘uncleansed or unpurified,’ designates it as the worst of all. It is seldom used, except for the purpose of plating, or rather washing, baser metals.

The tael of Sycee in the East India Company’s accounts was reckoned at 6s. 8d. sterling. When assayed in London, this metal is frequently found to contain a small admixture of gold. Mercantile account sales give the following average out-turn of China bullion remittances to London, Calcutta, and Bombay; that

100 taels of Sycee yield	£ 316 at 5s. an oz. including
	1½ per cent. for gold.
	3078 Sikka Rupees, or with
	charges 3062 Rupees, at Calcutta.
	3335 Bombay Rupees, or with
	charges 3302 Rupees, at Bombay.

(2757) *Copper coins of India.* Information regarding the copper coin in circulation throughout Central India is very limited, but it is well known that as much perplexity existed in the varieties of paisa, and in the greater range of their value, as in the coins of the more precious metals; so that every town and village almost had its separate currency, and its established nirkh, or, rate of exchange, with the rupee, to the great inconvenience of the traveller and of the poorer classes. In weight they vary from 280 grains (the Jaipuri, etc.) to 34 grains (the Maiwari): the former passing at about 35, the latter at 378, paisa for a rupee. From the small advantage of melting up copper money, it happens that much of the circulation in this metal is of very great antiquity; and not only many ancient Hindu coins are met with, but Bactrian and Roman copper coins are also frequently procurable at fairs and in the neighbourhood of old towns in Upper India.

The paisa was in some cases adopted as the unit for determining the larger weights of the bazars, as the Gorakhpur paisa, of which 530 were held equal to a passeri (five sers) at Gha-

## SILVER COINAGE OF INDIA.

zigue, and generally through the Benares province, 2,881 'chalans' of Fatehgarh in like manner were assumed as the weight of a man in that district. The Delhi paisa, coined till 1818, was twelve mashas or one tola in weight.

Most of the native paisa contain more copper in proportion to their value than the present Company's coin, which was, however, originally one tola in weight, and was gradually reduced to one hundred grains: it is at present in fact a government token, worth, intrinsically, less than its nominal value.

Within the Ceded Territories, the native coins still predominate, but the Company's paisa gradually to the westward, and the Sagar mint was for several years employed in converting the native copper money into Benares or trisuli paisa of one hundred grains weight, and sixty-four to the rupee. At Bombay, the old paisa were bought up by Government, for the purpose of removing them entirely from circulation, and substituting the new coin. The Bengal Government also adopted a measure to withdraw the trisuli paisa from circulation, in consequence of their becoming much depreciated in public estimation from a large admixture of spurious coin, and other causes; the Calcutta mint being ordered to grant sixty-four new paisa for seventy-two trisulis, for an amount not under twenty rupees in value brought for exchange.

(2758) *The Cowrie shell*, *Cypræa moneta*, has greatly fallen in value, in consequence of the facilities of commerce. In 1740, a rupee exchanged for 2,400 Cowries: in 1756 for 2,500; and recently in Calcutta, so many as 6,500 Cowries could be obtained for a rupee. In Madras, in 1850, Cowries have ceased to be used as money, but in Hyderabad of the Dekhan, in 1856, 2,688 Cowries were to be had for a rupee. Cowrie, in Persian, is simply khur-mohra, literally "jack-ass or mule shell" because mules are ornamented in that country, with trappings of shells, as a Gosain's bullock and riding horses are in India. In Arabic, it is known by Wuda, which Ibn-Batuta says were carried in large quantities from the Maldivé Islands to Bengal, where it was used as a coin, and therefore no doubt can be entertained that the *Cypræa moneta* was meant. It is employed throughout all Southern Asia, as an amulet, in sickness, and to avert the evil eye, provided the neck shell is split or broken. Among European nations these shells, on account of the fancied resemblance of their shape to that of the back of a little pig, are known by the names of Porceli, Porcellain, Porcellanen and Porcelaine, whence we have Porcelain, the glaze or varnish on the Chinese ware being similar to that of the Cowrie. If sound be taken, our English phrases, "not a Cowrie and not a cash" would seem derived from these two minute Indian monies.

## SILVER COINAGE OF INDIA.

(2759) *Dam*, دام A copper coin of India, now obsolete. In Akbar's time, forty dams of copper, were equivalent in account to one rupee, and the dam of copper is itself defined at five tanks, or 1 tola, 8 mashas and 7 ratis in weight, which at 186 grains per tola is equal to 323.5625 grains.

There seems to have been 9.29 chitals in each dam, and in the Shir Shahi rupee 371.8 chitals, instead of the old 320 divisional coins of that name and value, which went to the lighter silver piece of former days. In the Ayeen-i-Akhbaree, and in most Revenue accounts, the Dam is considered the 40th part of a rupee: but to the common people it is known as the 50th of a Tuka: 25 therefore go to a Pysa, and 12½ to an Adhela.

(2760) *Denar*, دينار A Persian gold coin, from the latin *denarius*.

(2761) *Dilli-All*, دلي ال or *Dhili wal*. دھلي وال In A. H. 614, the ordinary coin of the country about Delhi. "The original currency, it is supposed, corresponded with the billon money of Prithui Raja and others, which was imitatively adopted by the Mahomedans in the early days of their occupation of Hindustan.

(2762) *Dirham*, درهم An Arab Persian silver coin from the latin *drachma*.

(2763) *Dumree*, دمري Hind. Dumree is commonly known as a nominal coin, equal to 3¼ or 3½ Dams; or between 2 and 3 Gundas: so that a Dumree varies from 8 to 12 cowries according to the good will and pleasure of the money changers—p. 92.

(2764) *Fals*, فلس An ancient Arabic copper coin, named from the Roman *folius*.

(2765) *Ganda*, گنده Hind. See CASH

(2766) *Indian System of Coinage and Currency, in India.*

The silver rupee was introduced according to Abul Fazl, by Shir Shah, who usurped the throne of Delhi from Hamayun in the year 1542. Previous to his time, the Arabic dirham (silver drachma), the gold dinar (denarius auri,) and the copper fals (folius), formed the currency of the Moghul dominions. Shir Shah's rupee had on one side, the Mahomedan creed: on the other the Emperor's name and the date in Persian, both encircled in an annular Hindi inscription. Since the same coin was revised and made more pure in Akbar's reign, we may assume the original weight of the rupee from Abul Fazl's statement, to have been eleven and a quarter mashas. Akbar's square rupee, called from its inscription, the Jelali, was of the same weight and value.

## SILVER COINAGE OF INDIA.

This coin was called Char-yari, from the names of the four friends and immediate successors of Mahomed, Abu-bakr, Omar, Osman, and Ali, being inscribed on the margin. This rupee is supposed by the vulgar, to have talismanic power.

Concerning the weight of the Mashas of the Mahomedans, some difficulty prevails, as this unit now varies in different parts of India. Mr. Colebrook makes it seventeen grains and three-eighths nearly: but the average of several gold and silver jehalis of Akbar's reign, found in good preservation, gives 15.5 grains, which also agrees better with the actual masha of many parts of Hindustan. By this calculation the rupee originally weighed 174.4 grains troy, and was of pure silver or such as was esteemed to be pure. The same standard was adopted by the Emperor Akbar, and accordingly we find coins of Akbar's reign dug up in various places weighing from 170 to 175 grains. Cabinet specimens of Jahangir, Shah Jahan and Aurungzib, have also an average weight of one hundred and seventy five grains pure, and the same prevails with little variation up to the time of Mahomed Shah, in the coins of opposite extremities of the empire; or struck in the Subahs, of Surat, Ahmedabad, Delhi and Bengal, as in the Akbari, Jahangiri, Shah Jahani, Delhi Sonat: Delhi Sonat Alingir: Old Surat Rupee: Murshidabad, Persian Rupee of 1745: Old Dacca Mahomed Shahi, Ahmad Shahi and Shah Alam of 1772. The Moghul emperors thus maintained a great uniformity in the currency of their vast empire, and they were very tenacious of their privilege of coining. On the breaking up of the empire in the reigns succeeding Mahammud Shah, numerous mints were established by Ministers and by the Viceroy of the principal Subahs, who were assuming independence, and the coin was gradually debased as the confusion and exigencies of the time increased. The Maratti and other Hindu states also established mints of their own, retaining, for form sake, however, the Emperor's name and superscription, as a titular avowal of Delhi supremacy. As the English dominion spread, these differences gave rise to the difference in the currencies of the English provinces, and by a happy chance brought those of Madras, Bombay, Farrukhabad to a close approximation. Regulation XXXV. of 1793, was the first of those of the Company which treats of mint matters. At that time, the differences in the values of the currencies were very great, but the dates of the coinage on each coin facilitated the work of the Sirrafs or money-changers in applying the batta to which the known debasement of each coin entitled it. In 1793, the Company resolved to remedy the inconveniences which had thus arisen, by declaring that all rupees coined for the future should bear the impression of the 19th year of

## SILVER COINAGE OF INDIA.

Shah Alum, and thus by its adoption at that early period, it happened that the Sikha rupee was the only one of the Company's coins which retained the full value of the original Delhi rupee. About the same time, the Surat rupee of the Moghul Emperor, weighing 178.314 grains, was adopted as the currency of the Bombay Presidency. It contained 172.4 pure, and was thus nearly equal to the Delhi rupee. From depreciations made in the Surat coin, by the Nawab, the coinage at Bombay ceased for 20 years, but in 1800, the Surat rupee was ordered to be struck at Bombay, and from that date it became fixed at 179 grains weight, 164.74 pure, and the Muhr was equalised in weight thereto. Lastly in 1829, under orders from the Home Government, the currency of the Western Presidency was equalled with that of Madras by the adoption of the one hundred and eighty grain rupee and muhr. The Arcot rupee, in 1788, still retained 170 grains of pure silver, and subsequently when coined at the mint of Fort St. George, it had a weight of 176.4 grains or 166.477 grains pure, until the new system was introduced in 1818, and the Madras one hundred and eighty grain rupee was established.

The former inscriptions upon the Company's gold and silver coins were in Persian, as follows.

*Obverse* of the Sikha rupee struck at the Calcutta mint.

حامی دین محمد سایه فضل اله سکه زد  
بر هفت کشور شاه عالم بادشاه

Hami-i-deen-i-Mahomed, Sayah-i-Fazl Oollah Sikkah zad bar haft Kishwur Shah Alam badshah. Defender of the Mahomedan faith, reflection of divine excellence, the King Shah Alam, has struck this coin to be current throughout the seven climes. *Reverse*.

ضرب مرشد آباد سنه ۱۹ جلوس میمنت  
مانوس

Struck at Murshidabad in the year 19 of his fortunate reign.

On the rupee of the Western Provinces, coined at the late mints of Farrukhabad and Benares, and at the Sagar mint, the obverse had the same inscription, but on the reverse the date and place of coinage was different.

ضرب فرخ آباد سنه ۴۵ جلوس میمنت  
مانوس

Struck at Farruckhabad in the year 45 of his prosperous reign.

The Madras Rupee had a dotted rim on the face, and an indented cord milling: that coined in Calcutta had an upright milled edge: it has the symbol of a rose on the obverse. The inscriptions are as follows:—

سکه مبارک بادشاه غازی عزیزالدین  
محمد عالم گیر

## SILVER COINAGE OF INDIA.

The auspicious coin of the warrior King Aziz ood Deen Mahomed Alungir. (the father of Shah Alum).

ضرب ارکات سنه ۲۰ جلوس میمنت مانوس  
Struck at Arcot in the 20th year of his auspicious reign.

The Bombay coin had a plain edge and the following legend.

سکه مبارک شاد عالم بادشاد غازی ۱۲۱۵  
The auspicious coin of the warrior King Shah Alum, 1215.

ضرب سورت سنه ۱۴۶ میمنت مانوس  
Struck at Surat in the 46th year of his propitious reign.

As before explained, the Bombay, the Madras, and the Farrukhabad or Sonat rupee had fortuitously happened to be of nearly the same intrinsic value.

	Pure contents.
Arcot rupee .. .. .	165 grains.
Bombay rupee ... .. .	164.7 „
Farrukhabad rupee ... .. .	165.2 „

The alteration of the standard of purity in 1813, did not affect the proportion of pure metal, and when the Sagar mint was established in 1825, it was ordered to coin the new Farrukhabad rupee of 120 grains weight the same as the standard of Madras, or containing 165 grains pure.

The inscriptions on the Current Company's now Her Majesty's Silver Rupee are as follows—  
Obverse. Victoria Queen.

Reverse. East India Company, 1840. One Rupee

It is milled upright on the edge.

(2767) *Masha*. Hind. A weight in India varying from 14.687 to 18.5 grains troy: the average being 15½ grains. The rupee of Akbar which was based upon that of Shir Shah weighed eleven and a half mashas.

(2768) *Muhr* or Mohur from Muhr, Hind.; a seal, is a gold coin of value fifteen or sixteen rupees.

(2769) *Nepal coins*. Nepal was conquered by the Goorkhas in the Newar year 883, corresponding with A.D. 1768. Prior to this epoch, the valley of Kathmandu was divided into three sovereignties, Patan, Bhatgaon and Kathmandu, each governed by a Rajah. Hence on the Newar coins, three series of Rajas names are found, those of Bhatgaon being generally distinguished by a shell; those of Patan by a tirsool, and those of Kathmandu by a sword.

The old coins of the Mals or Newar Rajahs, are much valued for their purity, and are worn by the women, strung to necklaces or armlets, as tokens in memory of their ancestors.

All money current north of the valley of Nepal, as far as the boundaries of Chinese Tartary, was formerly coined by one or more of the Ne-

## SILVER COINAGE OF INDIA.

pal Rajahs, this was a source of considerable profit to them, the Bhooteahs giving them weight for weight in silver and gold dust: but Ranjet Mal, the last reigning Raja of Bhatgaon, sent them such base coins as to occasion a decrease of nearly one half of their intrinsic value, which was no sooner discovered by the Bhooteahs than a desertion of the mint took place, and there has been no more Bhote coinage made in Nepal. The Bhooteahs who now visit Nepal for trade, profit by this spurious coin, which they take in exchange for their goods at five gandas per muhr, and they pass off in their own country as of full value or ten gandas. As the Bhooteahs have no other currency they are compelled to cut them into halves, quarters, and eighths. They are the only coin current in Lassa.

The Nepalese procure all their silver from China, in the form of stamped lumps, as they are current in Lassa: for the Tibetans generally follow the Chinese custom in their money transactions, of paying and receiving by weight, and the merchants carry scales with them for the purpose. Since the Goorkha conquest the Vikrama era, has superseded that of Newar for ordinary purposes, and the Saka, commonly used in Hindustan, has been introduced upon the Nepalese coins.

(2770) *Pagoda*. A Portuguese appellation of a gold coin, the Hun, derived from the pyramidal temple depicted on one side of the coin. The proper Hindu name is Varaha "wild boar," and doubtless originated in a device of the Boar incarnation or Avatar of Vishnu upon the ancient coinage of the Carnatic, for the same figure appears as the signet of the Rajas of that country, in some old copper grants of lands in the Mackenzie collection. The Hindu name probably varied according to the image of the coin: thus we find the Rama tanka having the device of Rama and his attendants; and the Matsya Hun of Vijayanuggur with four fish on the obverse. Other Pagodas have Vishnu, Jagannath, Venkateswar, &c., on them: those with three Swamis or figures are of the best gold, and are valued ten per cent. higher than the common pagoda. Hun is the common term used by the Mohamadan writers, and indeed generally by the natives, for the pagoda. It signifies "gold" in the old Carnatic language.

The Hun was subdivided into fanams and kas. Fanam or more properly panam is identical with the word pan, known in Bengal as one of the divisions of the Hindu metrical system, now applied chiefly to a certain measure of kauris and copper money. The old fanam was of gold only, and was the one-sixteenth of a hun. In the Lilavati we find 16 pana = 1 dharan;

16 dharan = 1 nishk,  
where the dharan (or dharam) seems to accord

## SILVER COINAGE OF INDIA.

with the hun, which is identical in weight with the Greek drachma. The Ikkeri Pagoda contains sixteen fanams: that of Vararai and Anandru, fourteen, and the Kalyan Pagoda twenty-eight. The division adopted by the English was forty-two.

(2771) *Pai*. پاي Hind. A small copper coin in Indian currency, the third part of a pice and twelfth part of an anna.

(2772) *Pice*. پيسا *Paisa*, Hind. A copper coin, the one fourth part of an anna.

(2773) *Panna*. The standard of Panna under the Peishwa, was called the Ankusi rupee from انكس *Ankus* the instrument used by the Mahout to guide the elephant; probably a symbol marked on the coin.

(2774) *Parthian or Arsakian Monarchy*. This was erected by Arsaces, who filled the office of Satrap in Bactria, in the year 256 B.C. Vaillant wrote a history of this powerful dynasty and endeavoured to classify the coins of the twenty-nine Arsacidæ kings. It was subsequently absorbed in the Persian Empire in the reign of Alexander Severus, A.D. 226. Their coins have often been found in Southern Asia, the greater number having the Greek word *Arsakoy*, with different epithets.

(2775) *Persian Ancient coins*. According to Marsden, it was not until the Kalifat of Abdool-Malik, in the year of the Hijra 76, (A.D. 695) that a distinct coinage was instituted with a view of superseding the currency of Greek or Byzantine, and Persian, gold and silver.

(2776) *Pool*. پھول *Pehlvi* or پول *Phool*, Parsi. Obolus et res quævis obolo similis ut squama piscis, simil. فلووس (falooos) Borhani Katin. Inde پھولي Be Poollee: Abul-ool-Malik, n. c. Pecuniæ defectus." Abul Fazl says that the پول Pool of olden days was equal to four tolas, Ferishta again gives 1 or  $1\frac{3}{4}$  tolas.

(2777) *Rati*. رتي Colonel Anderson, considers the rati may be assumed as high as 1.93 grains, and the masha at 15.44 grains.

*Rupee*, روپيه *Rupiya* Hind. A silver coin current in India value about two shillings: it derives its name from the Sanscrit.

(2778) *Sanat*. سنه Arab. year, generally used in coinage.

(2779) *Sikka*, سكه Hind. A coining die, applied to a coin formerly current in India.

(2780) *Thibet*. Mr. Cosmo de Koros states that the English rupee circulates freely through Western Thibet. The common Chinese brass money, with a square hole in the centre, is like-

## SINGAPORE.

wise current in Lassa, as generally through the whole of the Chinese empire.

(2781) *Tola*. تولا Hind. A weight in India, equal to 180 grains troy, the weight of the present rupee.—*Prinsep's (Thomas,) Indian Antiquities, Vol. I, pages 1, 2, 10, 17, 18, 21, & 40. Vol. II. pages, 3, 4, 8, 11, 21, 22, 31, 32, 33.*

(2782) *SHAH-ZOUNG*. BURM. ALOE. This occurs in many varieties, and is used in Burmah both for medicine and chewing with the betel.—*Malcom, V. 1. p. 183.*

(2783) *SIALKOT*, one of the most ancient of forts and cities of the Punjaub was founded by Rajah Sala Byne or Salivahanna, father of Rusaloo. The fort, which adjoins the city to the westward is a high, oblong mound, with rectangular defences of curtains and round towers, massively built of brick and mortar. Bactria or Indo-Greek coins are found in the ruins, but not in any numbers. The commonest perhaps is the copper coin of Apollodotos.—*Beng. As. Soc. Jour. No. of 1854 p. 146.*

(2784) *SILK COTTON TREE*. *Bombax ceiba*.

(2785) *SINAPIS*. The following species are cultivated at the Saharunpore gardens.

(2786) *Sinapis brassica*.

Kurm Kulla. | Badshahee Rai.

(2787) *Sinapis dichotoma*.

Suhota. Sighla. | Torcea Kalee Surson.

Much prized for its oil.

(2788) *Sinapis erysimoides*.

Race. | Mukura race.

(2789) *Sinapis juncea*.

Bunga Surson.

(2790) *Sinapis nigra*.

Race.

(2791) *Sinapis Rajika*.

(2792) *Sinapis ragosa*.

Bhoteah Race. | Badshahee Race.

(2793) *Sinapis Sinensis*. Tarantula mustard of Hindustan.

Surshuf.

(2794) *SINGAPORE*. This island consists of a number of low hills and ridges with narrow and rather swampy flats intervening. In several places the sea-face is elevated but the greater portion of the circumference is fringed by a pretty deep belt of mangrove forest. Bukit Timah is a granitic hill, about 530 feet high, but the rest of the island is composed of sedimentary rocks, amongst which sandstone occupies a prominent place. There are other elevations, on the island known as Oxleys, Scotts, Guthries, &c

## SINGAPORE.

hills. Singapore was first settled in A. D. 1160, by Sri Sura Bawana. From an inscription, now destroyed on a sandstone rock on a narrow point to the left of the entrance of the Singapore river, it would appear that Raja Suran of Amdan Nagara after conquering the state of Johore with his kling or Coromandel troops proceeded to Tamask, about A. D. 1201, returned to kling or Bejaneegar, and left this stone monument. Tam Sack is also called Singapura—*Pages 83 to 90 of No. III. Sept. 1847 of Jour. of Ind. Arch.*

From the above table we find that Singapore nutmegs average 14,533 nuts per picul being the mean of Messrs. Cuppage's, Martin's and Hewetson's plantations, and that the annual produce of the bearing trees is 366 nuts per tree or  $2\frac{1}{2}$  catties or  $3\frac{1}{2}$  lbs, but it must be observed that a great majority are only coming into bearing. For an estimate of the weight of Pinang nuts it will be found from the data above given regarding that settlement for 1842 that in that settlement—there are 246 nuts to a tree which according to Mr. F. S. Brown's data hereafter given will make  $1\frac{1}{2}$  catties per tree or 2 lbs, but the same remark is applicable to Pinang that the majority of the trees were young. —Page 31.

(2795) SINGHPO. This is merely the word, for *man* in the languages of the tribes to whom it is applied. The great nursery of these tribes is along the Sgin-mae-kha, or great eastern branch of the Irawaddi. The wilder tribes are styled Khakhyens or Kakoos, and these sweep down on the Shan villages on which they exercise the greatest cruelties.

(2796) SITANG. The name of a river and valley of Pegu. The whole extent of the valley is about 350 miles of which one half lies within the British provinces of Pegu and Martaban.

(2797) SLOKA. This is a Hindu or Sanscrit word, a stanza, verse, &c., and probably the Malayas derived the term for their poetry styled "*Shair*" from the Arabs, and that of "*SLOKA*"

## SNAKES.

not so easily decided from its name, the word used here is *بربيت* Bar-beit which is from the Arabic bait بيت a couplet, but perhaps pantun itself is a Mlayan word.—*Jour. Ind. Arch. Vol. V. No. XI.*

(2798) SNAKES, remarks Viscountess Falkland, are really sensible to the charms of music. Educated snakes, who have been for sometime in the hands of a snakecharmer, are, of course, more susceptible than wild ones, and manifest their pleasure with less reserve, possibly, because they have become used to the musician's appearance, and are less inclined to try to escape, which would probably be the first impulse of the wild one. But all the family have naturally a taste for music, which may be proved by any one who has kept one of the harmless English snakes as a pet. The animal will always pay attention to any rather monotonous tune played on a flute or flageolet. This taste, by the way, is shared by many of the lizard tribe, by some pigeons, and very generally by hedgehogs; at least I have known three or four instances of it on the part of a hedgehog, kept in the lower story of a house, as an exterminator of blackbeetles and cockroaches. If after nightfall, when the hedgehog generally awakes and runs about in search of prey, he heard the sound of a violin or piano, he would always endeavour to make his way to the place whence the sound came, and if admitted into the room where the instrument was, he would stand entranced as long as the music continued. I mention this merely as a proof that several of the lower animals are attracted by music. But as regards Indian snakes, I have seen cases in which I had no room to doubt that the charmer, by his monotonous piping and drumming, did tempt really wild snakes from their hiding places. It is not often, however, that the charmer trusts entirely to his music. I have known them, when sent for to catch a large, and apparently very dangerous cobra, which had a hole in a dry stone wall, inconveniently near a gentleman's house, come provided with a tame cobra, whose fangs had been extracted. The cobra, was carried in a bag, very cleverly concealed under the arm of one of the charmers. The musician commenced piping, and all the spectators naturally directed their attention to him. He walked along the wall, and when he got near the supposed hole, piped more vigorously than before, and directed his own eyes and those of the spectators to a particular spot. On a sudden his accomplice gave a loud cry, and on looking at him, he was seen on the ground, grasping the neck of a large cobra, which he appeared to have seized as it was in the act of issuing from a hole in the wall, and whose tail was twisting round the man's arms and body. The other charmers came to his aid, and the snake was at length duly

“The imposture was discovered by the gentleman who owned the house insisting on shooting the snake. The charmers remonstrated, said ‘it was their god, had come out in consequence of their invocations, and would, if killed, haunt and ruin them, &c. The gentleman was obstinate, but at last told the charmers he would spare their snake, if they confessed the cheat he suspected. This they did, and showed him the bag in which the reptile had been concealed under the arm of one of their number, and satisfied him that the snake was destitute of fangs, and must therefore have been previously caught, and deprived of his weapons of offence.

“There is much which our philosophy has yet to learn, relative to the habit and tempers of these reptiles, and there is no doubt that there are particular individuals who are very little obnoxious to snake bites; just as there are particular people whom bees will never sting. She learned two very decided and well authenticated instances of this. One was a halfwitted boy of the wild tribe of Bheels, in Candeish. He was found by his relations playing with wild snakes, and had the power of attracting and taming them. He had numbers of all kinds of snakes in the jungle, near the hut where his parents lived, and these snakes would come to him and allow him to handle them with impunity. After some months he began to be known to the people round about as a prodigy, but as the part of the country where he lived was very remote, it was long before his fame spread to any distance; and soon after he had been heard of by the government officials, and official enquiry had been made to an extent sufficient to verify the main facts of the story, the poor boy was bitten by one of his favourites and died. “The other case occurred in the Sattara territory, about twenty-five years ago. It was noised abroad that the son of a Brahmin, not far from Waee, had the power of attracting the most venomous snake, and handling them with impunity. Numbers visited him, and seeing the story was true, spread his fame, and his relations finding that his reputation was likely to be profitable to them, added all sorts of marvels to the current tales. He was one of the promised avatars of the god Crishna, which are yet to come. He was to restore Hindooism in its purity, and re-establish Brahminical superiority in the Deccan. Thousands flocked to see him, and pay their respects, and bring oblations; and so great was the excitement, that the Raja of Sattara and the English Government officials got alarmed. The poor boy however, like the Candeish Bheel, was not permanently proof against snake bites, and was bitten and died just when his village had become the point to which every devotee in the Deccan was hastening, and the excitement subsided as quickly as it arose.

“It may be mentioned that a snake visiting

a house is always looked on as a sign of luck; and when a snake discovers how to get at the eggs and milk in the larder, no native will on any account, kill what he regards as the good genius of the house” — *Chow-Chow*, page 54.

(2799) SOLIMAN. A Mahomedan merchant who voyaged to India and China, in the beginning of the ninth century. His principal establishment was probably at Busrah.—*India in the 15th Century*.

(2800) SOLOR, is an island lying to the east of Flores and to the north of Timor, under which Presidency it is placed. The inhabitants of the coast of this island are Mahomedans in name, but they are nevertheless hard arrack drinkers, and gain their livelihood by fishing, the produce of which they exchange with the mountaineers for maize, the production of the ground, which the population cultivate for their subsistence, the soil there being of too volcanic a nature to grow rice.

These inhabitants of the shore are hardy mariners and fishers, and think nothing of approaching the whale with their little boats, eight feet long, to attack the unwieldy monster and tow him to the shore. The village which most applies itself to the whale fishery is Lamakera on the north east part of the island of Solor, and lying within the Strait. It is the largest, most prosperous and most populous. The four other Mahomedan villages are Layayong, Andanara, Lamahala and Trong, which three last are situated on the island Andanara.—*Journ of the Indian Archipelago*, December 1850, p. 767.

(2801) SOO-BAN. BURM. Is a shrub exceedingly prized by the Burmans, as yielding the best red dye of any wood they have. It is sold at a tical per viss, and seems rather rare. The leaves are a favourite article for curry.—*Malcom Vol. I. p. 191*.

(2802) SOREX. THE SHREW. The following Memoir on the Indian species of Shrews is from the pen of Edward Blyth, Esquire. As an incentive, he says, to the investigation of some of the most imperfectly known of Indian mammalia, and not the most inviting of groups to amateur students, we shall here endeavour to bring together, and to reduce or digest into intelligible form and order the scattered materials available for a Monograph on the Indian Shrews. It may lead to the discovery of additional real species, and probably to the diminution of the number of present supposed species; besides conducing to the further elucidation of those at present known and recognized, and especially to a better knowledge of the extent of their geographical distribution.

In general, the Shrews of tropical and subtropical countries are distinguished by their comparatively large size, and slaty hue of every shade from pale grey to black, with rufous tips to the

## SOREX CÆRULESCENS.

fur more or less developed, though in some scarcely noticeable; [Note. In at least some species, the rufous tips would appear to increase with age; and, to a considerable extent, the colour of these animals is darker, according to the increase of altitude inhabited by a species.] The ear-conch is conspicuously visible above the fur; the tail thick, tapering, and furnished with scattered long hairs, which certain species also exhibit upon the body; and the teeth are wholly white. [Note. While preparing this memoir, we discovered a remarkable exception in the instance of *SOREX MELANODON*, N. S.] and of the following type of structure. The superior front-teeth or *quasi-incisors* (vide J. A. S. XX, 164), are large and strongly hooked, and much longer than their posterior spur; while the inferior have rarely so much as a trace of serrated upper edge: of four upper præmolars anterior to the *canassiez*, the first is large, the second and third are much smaller, the fourth is diminutive, and the third exceeds the second. This group of Shrews is familiarly exemplified by the common large musk Shrews of Asia and Africa, and constitutes the restricted *SOREX*, L. (v. *Pachyura*, de Selys Longchamps.) [Note. Certain small species of temperate climates were detached by Wagler from the ordinary Shrews of those climates (with pious tipped teeth, &c.) by the name *CROCIDURA* (v. *Suncus*, Ehrenberg, apud Gray); e.g. *S. ARANEUS LECCODON*, *S. ETRUSCUS*, &c., but we are not aware that these are separable from the above; and certainly the various Pygmy Shrews of India are typical *SORICES*, except that some only of them want the odoriferous glands on the sides of the body.

N. B. In the 'Report on the Quadrupeds of Massachusetts,' published by the Government Commissioners of the Zoological and Botanical Survey of the State (Rs. 40), the extraordinary statement is made by Mr. E. Emmons, that "In the specimens of *Sorex* which have fallen under my observation, I have not been able to discover, even with the microscope, any nostrils, the termination (or the extremity) of the nose being apparently an imperforate membrane." Upon reading this, we examined several species (large and small) preserved in spirit; and easily detected a lateral valvular orifice, which, on pressure of the snout above, was shewn to be perforate by the fluid oozing through. Could Mr. Emmons have tried so simple an experiment?

The Indian species are as follows.

(2803) *SOREX CÆRULESCENS*, Shaw.

*Sorex Pilorides*, Shaw:

*Sorex Giganteus* Is. Geoffroy.

*Sorex Murinus*, L., apud Gray: figured in Hardwicke's *Ill. Ind. Zool.* as

*Sorex Myosurus*, Pallas; whence probably

*Sorex Myosurus*, apud Walker, in *Calc. Journ. Nat. Hist.* III. The common Musk

## SOREX CÆRULESCENS.

Shrew, or (*vulgo*), 'Musk Rat,' of Bengal, &c. (but very different from the 'Musk Rat' or *Muskquash*—*FIBER ZIBETICUS* of N. America, which is a rodent nearly affined to the *Voles*—*ARVICOLA*).

This animal is described by Mr. Hodgson in the *Ann. Mag. N. H.* XV, 269 (1845); but the length of the tail (as given),  $3\frac{1}{8}$  in. is possibly a misprint for  $3\frac{5}{8}$  or  $3\frac{7}{8}$  in., or more than half of the length of the head and body, which is given as 6 in. Number of caudal vertebræ, 24. Total length of skull of adult male, with front-teeth *in situ*, somewhat exceeding  $1\frac{1}{8}$  in.; of female, somewhat under greatest breadth of skull of former,  $\frac{1}{8}$  in.; of latter,  $\frac{5}{8}$  in. Colour uniform pale grey, slightly tinged with ferruginous, and more conspicuously on the lower parts; the naked parts flesh-coloured.

This is the common large Musk Shrew of Bengal, Nepal, and we believe the valley of Assam; becoming rare in Sylhet; and wholly disappearing in Arakan. In Nepal, Mr. Hodgson styles it "the common house Shrew of the plains, and also of the hills, up at least to 6000 feet." We have seen specimens from the neighbourhood of Agra: but whether, it be the common Musk Shrew of S. India is doubtful on present evidence; though Dr. Kelaart's description of the Cinghalese animal corresponds. It certainly does not appear to inhabit the eastern coast of the Bay of Bengal, from Arakan to the Straits of Malacca. Dr. Horsfield gives as its habitat "India generally, and the eastern islands;" and he notes a specimen from Butan, presented to the India-house collection by Major Pemberton. 'We' suspect that its reputed existence in the Malay countries, needs confirmation.

In addition to the names above cited, Dr. Gray, in his Catalogue of the specimens of mammalia in the British Museum (1843), refers the following name and synonymes to this species.

*Sorex Murinus*, L.:

*Sorex Myosurus*, Pallas:

*Sorex Indicus* et *Capensis* Geoffroy.

*Sorex Sonneratii*, Is. Geoffroy:

*Sorex Crassicaudatus*, Lichtenstein:

*Sorex Nipalensis*, Hodgson, and

*Sorex Moschatus*, Robinson.

The last two are merely MS. names; and indeed the Zoological appellations in Mr. W. Robinson's 'descriptive account of Assam' are given pretty much at random, and would establish a most extraordinary community of species among the mammalia of that country and of Europe! He gives, "Genus *MYGALE*, *Sorex Moschatus*, Cuvier. The common Musk Rat." Now *Sorex moschatus*, L. (nec. Cuvier), is the type of the genus *MYGALE* of Cuvier; altered to *MYOGALEA*, Fischer (*Myogale* apud Ruppell), because pre-occupied by Linnæus for a well known genus of Spiders; and *Myogalea*

## SOREX INDICUS.

**MOSCHATA**, is a Russian animal, generically differing from Mr. Robinson's Musk Shrew. Nevertheless, his adoption of the term *moschatus* would seem to indicate the rankly smelling *S. Cærulescens*, rather than *S. Murinus* (v. *myosurus*), which is the only Shrew mentioned in Prof. Walker's list of the mammalia of the same province.

(2804) **SOREX INDICUS**, Geoffroy, v. *S. Sonneratii*, Is. Geoffroy, is accepted as a distinct species from *S. Cærulescens* in Dr. Horsfield's Catalogue of the specimens of Mammalia in the India House Museum (1851); and a specimen is noted from the Dukhun, presented by Col. Sykes, and the following habitat given for the species - "Continent and islands of India." Col. Sykes terms it the Cheechonder of the Mahrattas; being the same name which is applied to *S. Cærulescens* in Bengal, spelt *Choochundr* by Dr. Cantor (*J. A. S.* XV, 191), and the latter author gives "*Chinchorot* of the Malays of the Peninsula" as the name of the very distinct species referred by him and others to *S. MURINUS*, L.; which latter was originally described from Java. According to Colonel Sykes, these troublesome and disagreeable animals are very numerous in Dukhun, but much more so in Bombay. The sebaceous glands in an old male were observed to be very large, and the odour of musk from them almost insupportable; while in an adult female the glands were scarcely discernible and the scent of musk very faint. It is tolerably strong in the female of *S. Cærulescens*; though more or less so, perhaps, with reference to sexual condition. "The **SOREX INDICUS** and *S. GIGANTEUS*," it is added, "are regarded by Col. Sykes as specifically identical, he having killed them in the same room, and seen them frequently together." (*P. Z. S.* 1831, p. 99). Prof. Schinz accordingly assigns *S. GIGANTEUS*, Geoff. *Ann. du Mus.* XV. pl. 4, of 3, as a synonyme of *S. INDICUS*: but the reference is erroneous, the *Memoires du Museum*, tom. XV (to which we have not access), being probably intended. *S. GIGANTEUS*, Is. Geoff, *Voy. de Belanger*, refers to *S. cærulescens* of Bengal.

According to M. Isidore Geoffroy, the *S. INDICUS* (his *S. Sonneratii*) is a smaller animal than *S. Cærulescens* (his *S. Giganteus*), with tail forming always a *quarter* of the entire length. Length of the head and body of adult, a little under 4 in. (Fr). Fur ashy, washed with russet-brown; and pale ashy below. Inhabits the Coromandel coast, and also the Mauritius. If truly a distinct species from *S. Cærulescens*, its natural habitat is probably India: but we have vainly sought for information of such an animal.

In Dr. Ruppell's printed Catalogue of the specimens of mammalia in the Frankfort Museum (1842) examples referred to *S. INDICUS*, L. (Fr. *Cav. Mamm.* 11, t. 28), are noted from Java, and also from Massoua and from Suez; and a sup-

## SOREX MURINUS.

posed variety termed by him *S. INDICUS*, var.; *cinereo-ænea*, from Schoa: and he elsewhere suggests that these animals have probably been introduced by the shipping from S. E. Asia and its islands, and so found their way over to Schoa, where a different climate had affected the colouring of the fur. On ship-board they could of course subsist on *BLATTÆ*: but their presence (certainly that of the foetid *S. Cærulescens* of Bengal) would scarcely escape remark, the more especially as that of a single individual might seriously damage a whole cargo; besides the obvious necessity of both sexes being required to continue the race, a condition most likely to be fulfilled by the conveyal of a pregnant female with her future litter 5 or 6 in number.

(2805) **SOREX CRASSICAUDUS** (nec *crassicaudatus*), Lichtenstein, refers to a Musk Shrew inhabiting Egypt, and stated to be common about Suez; which may therefore be presumed identical with Dr. Ruppell's *S. INDICUS* from Suez; and the description certainly seems to approximate that of *S. Cærulescens* (length  $5\frac{1}{2}$  in.; tail  $2\frac{3}{4}$  in.): and *S. CAPENSIS*, Geoffroy, is termed *S. FRANCICUS* by Prof. Schinz, who gives Mauritius as its habitat (length 3" 8"; tail 1" 9"). The most notable identification is that of Dr. Ruppell's specimens from E. Africa and from Java, presuming the latter to be really from that island.

(2806) **SOREX MURINUS**, L. *S. myosurus*, Pallas: *S. cærulescens*, var., Raffles: *S. Griffithii* (?); Horsfield: the common Malayan species originally described from Java, and by Dr. Cantor in *J. A. S.* XV, 191, and thus denominated by him after Prof. Schinz (*Synopsis mammalium*), who states it to inhabit Java, Sumatra, Borneo, Celebes, Amboyna, Japan, Bengal, Abyssinia, and the Cape of Good Hope. We have italicized the habitats which probably need verification: and the Society possesses specimens from the Arakan and Khásya hills, which accord with Dr. Cantor's description, *l. c.*; but less so with M. Geoffroy St. Hilaire's figure, in the *Annales du Muséum d' Histoire Naturelle*, tom. XVII, pl. 3, f. 2, which may nevertheless be intended to represent the same species. As compared with a mature female from Arakan, taken out of spirit, the ears in M. Geoffroy's figure are represented too small, and neither the snout nor tail is sufficiently elongated. Length of this Arakan female—head and body 5 in., and tail 3 in.: hind-foot (with claws)  $\frac{7}{8}$  in. Unfortunately, we have no Malayan specimen for actual comparison: but there is every reason to suspect that this species replaces *S. Cærulescens* along the whole eastern coast of the Bay of Bengal, and thence through the hilly country northward, to that skirting the valley of Asam. Dr. Horsfield

## SOREX SERPENTARIUS.

mentions a Nepalese specimen, presented to the India House museum by Mr. Hodgson: but this species is unnoticed in the latter gentleman's Catalogue of Nepalese animals and especially in his descriptive notices of the Nepalese Shrews; *Ann. Mag. N. H.* XV, 269. With the exception of the small *S. TENUIS*, *S. Muller*, from Timor, it appears to be the only well established species of Shrew throughout the great oriental Archipelago. In the Tenasserim provinces, the Rev. J. Mason states—"We have at least two species of Musk Shrew, both of which emit an offensive odour." (*Qu.* *S. MURINUS* and *S. SERPENTARIUS*?) In *S. MURINUS*, according to Dr. Cantor, "the smell of musk, emitted by the adult animal, and which in the young is barely perceptible, is much less intense than in the Bengal Musk Shrew." *S. SERPENTARIUS*, according to Dr. Kelaart, has a powerfully offensive musky odour. *S. MURINUS* has larger ears than *S. CÆRULESCENS*; and Dr. Cantor describes it as—"Dark brownish-grey above" beneath light brownish-grey. Feet and tail flesh-coloured in the living animal, changing to cinereous after death. In the young the colour is more of a bluish-grey, slightly mixed with brown on the back. A stuffed specimen from the Khasya hills has the fur longer and less dense than in *S. CÆRULESCENS*, the piles somewhat curly: and colour dark ashy at base, with rufous-brown tips which give the prevailing hue. A most obviously distinct species from *S. CÆRULESCENS*.

We suspect that *S. Griffithii*, Horsfield, of that naturalist's Catalogue of the specimens of Mammalia in the Honorable Company's museum, is no other than our presumed *MURINUS* from the Arakan and Khasya hills; although described from Afghanistan: because we saw a fine skin from Cherra Punji in the possession of the late Mr. Griffith, which was forwarded to the India-house by Mr. McClelland; and we have previously had occasion to remark that specimens of reptiles procured by Mr. Griffith in Afghanistan and in the Khasya hills, had manifestly become mixed and confounded; whence certain important mistakes concerning habitats. [Vide *J. A. S.* XXII, 413.] *S. Griffithii* is described to be allied to *S. MURINUS*; "but differing essentially by the uniform deep blackish-brown tint, and the shortness, delicacy, and softness of the fur. Colour deep blackish-brown throughout, with a slight rufous reflection in a certain light. Length of head and body,  $5\frac{3}{4}$  in.; tail  $2\frac{1}{2}$  in." Horsfield's Catalogue.

(2807) *SOREX SERPENTARIUS*, Is. Geoffroy: *S. Kandianus* Kelaart. Described in *J. A. S.* XXI, 350 from a skin sent by Dr. Kelaart as "the large godown Shrew of Kandy;" though scarcely corresponding with his indications, *J. A. S.* XX, 164. 185. A second skin of precisely the same species, and also an adolescent specimen entire in spirit, were

## SOREX NEMORIVAGUS.

subsequently forwarded from Mergui by Capt. Berdmore, as noticed in XXII, 412. In both adults, the tail (vertebræ) measures  $2\frac{1}{8}$  inch; and the head and body (allowing for some extension of the skin) about  $4\frac{1}{2}$  inch: "The Kandyan specimen is more rufescent than the others; but we can perceive no further difference whatever; indeed, to judge from the two Mergui examples, it would seem that this animal becomes more rufescent with age. Dr. Kelaart states that its odour is as offensive as that of the large Musk Shrew of Ceylon. The Coromandel coast and the Mauritius are given as its habitats. Colour duskyish-grey with dark rufous-brown tips to the fur, more or less developed according to age, and the under parts somewhat paler.

(2808) *SOREX SOCCATUS*, Hodgson, *Ann. Mag. N. H.* XV. 270. A Sikim specimen which we refer to this species, bears considerable resemblance to the last, but is a good deal darker, with well clad feet and tail; and the head and limbs are proportionally larger. Entire length of skull with front teeth *in situ*,  $1\frac{5}{8}$  inch; breadth  $\frac{9}{16}$  in., (nearly); entire range of upper teeth,  $\frac{5}{8}$  in., ditto of *S. Serpentarius*, barely exceeding  $\frac{1}{2}$  in. Tail (vertebræ),  $2\frac{5}{8}$  in.; compressed towards tip, which is furnished with a pencil-tuft of stiffish hairs. Mr. Hodgson thus describes his animal. "Size and proportions of *S. nemorivagus*, H. (nearly); but distinguished by its feet being clad with fur down to the nails, and by its depressed head and tumid bulging cheeks (mystacial region) Ears large and exposed. Colour a uniform sordid or brownish slaty-blue, extending to the clad extremities. Snout to rump  $3\frac{1}{2}$  in., tail  $2\frac{1}{8}$  in.; planta  $\frac{1}{8}$  in. This animal was caught in a wood plentifully watered, but not near the water. It had no musky smell when brought to me dead." Hab. Nepal and Sikim.

(2809) *SOREX NEMORIVAGUS*, Hodgson, *Ann. Mag. N. H.* XV. 279, Differs from the ordinary type "by a stouter make, by ears smaller, and less entirely nude, and by a longer and more tetragonal tail. Colour sooty-black with a vague reddish smear; the nude parts fleshy grey. Snout to rump  $3\frac{5}{8}$  in.; tail 2 in.; planta,  $\frac{1}{8}$  inch. Found only in woods and copices." Nepal, according to Dr. Gray, an example presented to the British Museum by Mr. Hodgson, as of this species, "is probably only a half grown specimen of *S. MURINUS*" (i. e. *CÆRULESCENS*)! [Note. We made a description of the identical specimen before it was taken by Mr. Hodgson to England; viz.—"Of a shining rufescent-brown colour, merely weaker on the under-parts. Length  $3\frac{1}{2}$  in.; of tail  $1\frac{7}{8}$  in.; fore-feet and claws  $\frac{7}{8}$  in.; the claws alone  $\frac{1}{2}$  in., and of a yellow colour, perhaps whitish in the fresh animal; hind-feet and claws  $\frac{5}{8}$  in."] The foregoing description should indicate a very different animal; but which might be mistaken for the young of *S. MURINUS* (*verna*), and such pro-

## SOREX PYGMÆUS.

bably is the supposed *S. MURINUS* from Nepal of Dr. Horsfield's Catalogue.

(2810) *SOREX HETERODON*, Blyth n.s. Very similar to *S. SOCCATUS* in general appearance, but less dark-coloured, with shorter fur, and pale instead of blackish feet and tail underneath; the feet, too, are broader, especially the hind-feet; and they have a hairy patch below the heel. The skull, of the same length as in *S. SOCCATUS*, and with equally large teeth, is much more narrow, and the upper quasi-incisors are conspicuously less strongly hooked than in that and other typical *SORICES*. From Cherra Panji, in the Khasya hills.

(2811) *SOREX NIGER*. *Elliot*; described in Dr. Horsfield's Catalogue (1851). "Length of the head and body  $3\frac{1}{2}$  in.; of tail  $2\frac{1}{2}$  in. Tail equal in length to the entire animal, exclusive of the head; gradually tapering to a point. Snout greatly attenuated. Colour blackish-brown, with a rufescent shade to the upper parts: abdomen greyish. From Madras', (*Qu. Madras Presidency?*).

(2812) *SOREX FERRUGINEUS*, Kelaart, *J. A. S. XX*, 185: *S. montanus* apud Blyth, (misled by a label), *ibid.* 163, vide *XX*, 350, note. Hab. Ceylon *N. B.* The dimensions of the specimen described in *J. A. S. XX*, 163, accord with those assigned by Dr. Kelaart to the next species; and he states that the two are nearly of the same size, and that the smell of the present species is very powerful.

(2813) *SOREX MONTANUS*, Kelaart (*nec* apud Blyth, *J. A. S. XX*, 163). Length of head and body  $3\frac{3}{4}$  in.; of tail  $2\frac{1}{2}$  in.; of hind-foot  $\frac{3}{8}$  in. Fur, above sooty-black, without any ferruginous smear; beneath lighter-coloured; whiskers long, silvery-grey: lower part of legs and feet greyish, clothed with appressed hairs. Claws short, whitish. Ears large, round, naked; the outer margin lying on a level with the hair of the head and neck, and being thus concealed posteriorly." Mountains of Ceylon ("the blackest Shrew of the highest parts of the island." Kelaart.)

Dr. Kelaart has lately forwarded an entire specimen in spirit of a young female Shrew found at Galle (!), though with the three pairs of inguinal teats well developed; which may prove to be the young of *MONTANUS*, but is perhaps distinct and new. If so, *S. KELAARTI*, Blyth. Colour uniform blackish above and below, slightly grizzled and glistening; the fur short and close, with scattered fine long hairs throughout (as described of *S. MONTANUS*). Length of head and body  $2\frac{3}{4}$  in.; of tail  $1\frac{1}{4}$  in.; and of hind-foot with claws  $\frac{5}{8}$  in.

(2814) *SOREX PYGMÆUS*, Hodgson *Ann. Mag. N. H.* XV, 269: *nec S. pygmaus*, Pallas: if the small European species referred by Schinz, Rüppell, and others to the latter be correctly identified, *S. PYGMÆUS*, Pallas, apud Schinz, is placed by the latter Zoologist among

## SOREX MICRONYX.

the species with brown-tipped teeth, and in the division of them which corresponds to *CORSIRA*, Gray; and the description—*caudâ basi contractâ auriculis brevissimis*;—will certainly not apply either to Mr. Hodgson's animal, or to various other minute Indian shrews hitherto undistinguished from it: and therefore Mr. Hodgson's name for the present species may stand, as he states the structure of the animal to be typical. Since writing the above, we have seen the figure of *SOREX PYGMÆUS*, Pallas and Laxmann (*S. minutus*, L., *S. exilis*, Gmelin, and *S. minimus*, Geoff.) in the *Act. Acad. Leop.* Vol. XIII, pt. 2, t. 25 (1827); and the species is widely different from all the pygmy shrews here described, and is evidently a *Corsira*. The following is his description—"snout to vent, less 2 in.; tail,  $1\frac{3}{8}$  in. head,  $\frac{1\frac{1}{8}}$  in.: palma,  $\frac{1}{4}$  in.: planta,  $\frac{3}{8}$  in. Structure typical, save that no odorous glands were detected, nor had the animal any musky smell. Colour sooty-brown, paler below. Naked parts of a dusky flesh hue. Hab. Nepal, where it "dwells in copices and fields, and is rarely found in houses."

Of numerous specimens of minute *SORICES*, from various localities, the only one which approaches to the above description is a species which we have just procured in Calcutta; curiously enough while engaged in the investigation of this particular group. It may be termed

(2815) *SOREX MELANODON*, Blyth, *n. s.*: from the remarkable colouring of its teeth, which are *piceous* and *white-tipped*; exhibiting thus the reverse coloration of those of *CORSIRA*, &c. Length of adult female  $1\frac{3}{8}$  in.; tail  $1\frac{1}{8}$  in.: hind foot and claws  $\frac{5}{16}$  in. Colour uniform fuscous, without any rufous tinge; scarcely paler below: the feet and tail subnude, save the usual scattered fine long hairs upon the latter; and, with the ears and snout, of a livid colour, paler below: claws white and distinctly visible. Procured by one of our museum assistants in his own house, where he states that he has observed and probably will obtain others.

(2816) *SOREX MICRONYX*, Blyth, *n. s.* length of head and body  $1\frac{5}{8}$  in.; tail somewhat exceeding  $1\frac{1}{8}$  in.: hind-foot and claws  $\frac{1}{2}$  in.: skull  $\frac{1}{2}$  in. teeth white. Claws with fine hairs impending them, and so minute as to be scarcely discernible without a lens. Fur of a paler and more chestnut brown than any other of these minute species examined, and also more silvery below. Feet and tail subnude, or thinly furred, shewing the colour of the skin through; browner above, whitish (or perhaps flesh-coloured) below. Of two specimens in our museum, one in spirit, the other now dried, the latter was obtained by the late Major Wroughton in Kemaon, the former by L. C. Stewart Esquire of H. M. 61st foot, at Landour; where he informs us he picked up many of them dead, on the surface of the snow during the severe winter of 1850-51.

## SOREX ATRATUS.

(2817) *SOREX PEROTTETII*, Duvernoy, Guérin's *Mag. de Zool.* 1842, livr. 8. We can only refer to Prof. Schinz's description of this species, which is as follows:—" *S. notæo saturate fusconigricante, gastræo canescente, artubus pedibusque pilosis, auriculis magnis, conspicuis.* Long. corporis 1" 4"', caudæ 11." From the Nilgiris. We have a Darjiling female which approximates this description, and may prove to be of the same species. Head and body 1½ in.; tail 1 in.; hind-foot and claws ¾ in. Skull somewhat exceeding ½ in. Teeth white. Colour uniform brown, with a slight tinge of chesnut; and scarcely paler below. Feet and tail distinctly furred, besides the usual scattered long hairs on the latter. Claws whitish and conspicuous. Tail brown above, pale and perhaps flesh-coloured beneath; more probably, however, of a livid hue; and tapering evenly throughout. If new, *S. Hodgsonii*, Blyth.

(2818) *SOREX NUDIPEDES*, Blyth. *n. s.* Remarkable for its naked feet and very large ears; also for the odoriferous glands on the sides being strongly developed, whereas we can detect them in no other of these minute species. Length of female, 1½ in.; tail, 1⅛ in.; hind-foot ¾ in. Ears conspicuously larger than in the others: tail almost nude, save of the scattered long hairs: and the fore-feet and toes of the hind-feet are conspicuously naked, and apparently flesh-coloured. Fur uniform brown above (like the back of *CORSIRA VULGARIS*), a little grizzled and glistening; the lower-parts with a silvery gloss: tail brown above, pale (probably flesh-coloured) below; somewhat thick and uniformly tapering. Specimen procured at Amherst (Tenasserim provinces).

(2819) *SOREX ATRATUS*, Blyth, *n. s.* Of this we have only a headless specimen which was found impaled upon a thorn by some Shrike. [Note The same fact we have observed in England of *LANIUS COLLURIS* and *CORSIRA VULGARIS*: these diminutive Shrews falling an easy prey to the "Butcher-birds;" while the larger members of the same genus are ferociously predatory upon any hapless birdlet they may chance to seize,—as is likewise the case with Moles and doubtless other soricidæ of adequate size and strength.] at Cherra Punji in the Khasya hills: but the species is obviously distinct from all the preceding. It is remarkable for its very-dark colour, extending over the feet and tail which is even *blackish underneath*. Length of tail 1 in.; and of hind-foot ¾ in. Fur blackish-brown above, a little tinged rufescent, and with dark greyish underneath; the feet and tail conspicuously furred, besides the scattered long hairs upon the latter.

Here may be noted, that the Society formerly possessed a specimen of one of these minute Shrews, which was found in a cellar in Madras, and was presented by Walter Elliot, Esq.;

## SOREX ATRATUS.

cal with *S. MICRONYX*; so that it could scarcely be so with *S. MELANODON* of Bengal: it was, however, darker than *S. MICRONYX*; and more probably *S. PEROTTETII* (*verus*), if not distinct from the whole of the foregoing. It is even probable that several more Indian species of these most diminutive of all mammalia remain to be discriminated. Upon minute comparison of five specimens in our museum, taken out of spirit and carefully dried for the occasion, we immediately detected four well marked species, and presently afterwards obtained the *S. MELANODON* fresh. It may further be remarked that we once found the nearly digested remains of an adult small white toothed *SOREX*, rather larger than a common Mouse, in the stomach of an *ELANUS* which was shot on the banks of the Hugli, about 15 miles above Calcutta: but we have since in vain sought to procure the species.

Another form of white toothed Shrew, with thick and tapering tail having scattered long hairs upon it, is exemplified by

(2820) *Feroculus*, Kelaart. Teeth small; the upper quasi-incisors shorter and less strongly hooked than in restricted *Sorex* with the posterior spur large; the lower quasi-incisors serrated, shewing two depressions and therefore a row of three coronal points four small upper præmolars preceding the *carnassiez*, the two medial being of equal size, the first rather large, and the fourth small. Feet remarkably large. The ear-conch scarcely visible above the fur.

(2821) *Feroculus Macropus*. *Sorex feroculus*, Kelaart; *S. MACROPUS*, Blyth, *J. A. S.* XX, 163. Length about 6½ in.; of which the tail is 2½ in.; hind-foot with claws nearly ¾ in.; the fore-foot ¼ in. broad, with long and but slightly curved claws, that of the middle digit ¼ in. in length. Fur somewhat long and very soft, uniform blackish, very faintly tinged rufescent; the extreme tip of the tail naked and of a flesh-colour. Inhabits Ceylon.

Another white toothed Indian Shrew exists in the *CROSSOPUS HIMALAYICUS*, Gray, to be noticed presently. We feel much doubt of its being correctly referred to *CROSSOPUS*. [Note. *MYOSOREX*, Gray, is founded on a Cape species, the *SOREX VARIUS*, Smuts, with ear-conch concealed amid the fur, and a slender tail (without scattered long hairs?) the teeth white, and the dentition slightly modified upon that of restricted *SOREX*: lower quasi-incisors "with an entire sharp upper edge."] The greater number of small Shrews inhabiting the temperate regions of Europe, Asia, and N. America, have the teeth always tipped with ferruginous or pitch-colour, a slender Mouse-like tail with no scattered long hairs upon it, and (save in *OTISOREX*) the ear-conch concealed amid the fur. There are two distinct types of dentition.

In one, the upper quasi-incisors are much longer than their posterior spur (as in restricted

SOREX); and the lower have but a single posterior spur more or less rudimental: the lateral small teeth which follow in the upper jaw are four in number (as in restricted SOREX); the first two being equal, the third somewhat smaller, and the last (as usual in all Shrews) minute. With this type of dentition we distinguish

(2822) SORICULUS, Blyth. With the hind-feet of ordinary form and proportions, unadapted for aquatic habits, and the tail tapering and a little compressed at its extremity.

(2823) SORICULUS NIGRESCENS; *Corsira Nigrescens*, Gray, *Ann Mag. N. H.* X, 261, (1842); *Sorex Sikimensis*, Hodgson, Horsfield's Catalogue, (1851). Length of head and body,  $3\frac{1}{2}$  in.; of tail,  $1\frac{1}{2}$  in.; hind-feet and claws  $\frac{5}{8}$  in. Number of caudal vertebræ 15 (besides the extreme tip). Colour throughout blackish, a little tinged with rufous; the feet and claws pale. Very common in Sikkim; and was formerly sent by Mr. Hodgson to the Society's Museum and also to the British Museum from Nepal.

(2824) *Crossopus*, Wagler (*V. Hydrosorex*, N. Duvernoy, and *Pinalia*, Gray). With the hind-feet large and ciliated, and the tail also compressed and ciliated beneath towards its extremity; in adaptation to aquatic habits. *N. B.* S. FODIENS, (*v. Hydrophilus*), Pallas, and other Water Shrews of Europe and N. America constitute the types of this division; and Dr. Gray refers to it a Himalayan species, which, having *white teeth*, we very much suspect will prove to differ in other and more important particulars; even though it may exhibit the *adaptive* characters of an enlarged and ciliated hind-foot and compressed and ciliated tail-tip. It is thus described.

(2825) *Crossopus Himalayicus*, Gray, *Ann. Mag. N. H.* X, 261 (1842). "Length of head and body  $5\frac{1}{2}$  in.; tail 3 in.; hind-foot  $\frac{3}{4}$  in. (nearly). Slate-coloured black, with scattered long hairs, which are longer and white-tipped on the sides and rump: lower part of the throat and the middle of the belly rusty-rusty-brown: tail elongate scaly, with appressed dark brown hairs above and elongated rigid whitish hairs beneath, and brown elongated rigid hairs near the tip: feet rather naked: whiskers numerous, elongate brown. *Teeth white*" probably from the neighbourhood of Simla or Masuri.

In the other type of dentition the lower quasi-incisors are distinctly serrated, with three or four coronal points; and the anterior point of the upper quasi-incisors is not prolonged beyond a level with its posterior spur: the lateral small teeth which follow in the upper jaw are five in number, and diminish gradually in size from the first backward. Tail cylindrical, not tapering and furnished with a stiffish brush at its extremity. Such is the common British land Shrew, *S. VULGARIS*, L. (formerly confounded by British writers with *S. ARANEUS*,

Schreber), and which is the type of *CORSIRA*, Gray (*V. Amphisorex*, No. 1, Duvernoy, apud Gray). There are many other species [Note. *BLARIA*, Gray, (*v. Blarina*, Lesson) is founded on *S. TALPOIDES*, Gapper, Zool. Journ. V, 23,] referred by Blainville to *S. brevicaudus*, Say; a N. American species, which, we believe, only differs from *CORSIRA* in the large size of its fore-feet, and in its very short tail: - and *OTISOREX*, Dekay, is founded on two minute N. American species, which do not appear to differ from *CORSIRA* except in having the ear-conch large and conspicuously visible above the fur. We refer to it doubtfully.

(2826) *Crossopus* (?) *Caudata*; *Sorex caudatus*, Hodgson, Horsfield's Catalogue (1851): for the description seems to indicate a species closely affined to the European *S. ALPINUS*, Schinz; a skull-less example of which from Mt. St. Gothard, is in our museum; and *S. ALPINUS* is ranged among the species having the *Corsira* type of dentition by Prof. Schinz in his *Synopsis Mammalium*: its tail however is naked and compressed at tip. "Length of the head and body  $2\frac{1}{2}$  in.; of the tail the same, slender, nearly naked, and very slightly attenuated. Colour saturate blackish-brown, very slightly rufescent in certain aspects. Snout moderately elongated, furnished at the sides with long delicate hairs."

We now conclude an effort at a *Conspectus* of the Indian Soricinæ, by soliciting aid from all (probably not many persons in India) who take any interest in the subject. It will suffice if specimens could be sent in spirit to the museum of the Society (if disembowelled, and the abdominal cavity cleaned of blood, so much the better for our present purpose, except with regard to the very diminutive species, examples of which are particularly acceptable); such being far preferable to badly prepared skins for being afterwards set up as stuffed specimens, besides permitting of much more satisfactory examination of their differential characters; and it is further desirable that three or four adults of each kind should be thus transmitted to supply our collection with skeleton and stuffed specimens, in addition to at least one to be retained entire in spirit. The *micro-mammalia*, as they have been designated (as Bats, Shrews, Mice, &c.) require to be thus amply represented in museums, for their specific distinctions to be rightly understood in many cases; and the chaos of Indian *MURIDÆ*, in particular, will never be reduced to systematic order, with the synonymes correctly adjusted, until such a tolerably complete collection of them from all quarters has been brought together.—*Journ. As. Soc. of Beng.* No. 1 of 1855.

(2827) *SOUTHWELLIA*\* *BALANGHAS*. China Chestnut: Seeds when roasted, highly palatable.

## SPIDER.

(2828) SOUNG-YA, BURMESE. This plant grows six or eight feet high. Fruit, the size of an apple, elongated, deeply fluted, brilliant yellow, contains ten seeds in five apartments. Chiefly used to acidify curry.—*Malcom. V. 1 p. 183.*

(2829) SPIDER: EPEIRA, species.

Capt. W. S. Sherwill communicated to Mr. Blyth, the following on the bird-devouring habit of a species of spider. This interesting communication on the contested subject of bird-eating spiders originated in his request that the author would commit to paper the observations of which he had assured him in conversation.—*E. B. Beng. As. Soc. Jour. No. VI. of 1850 p. 474.*

During one of my rambles in company with four other officers in the army, amongst the Karrakpur hills, in the immediate neighbourhood of Monghyr, on the Ganges, I fell in with several gigantic webs of a large black and red spider, which stretching across our path in many spots, offered from their great strength a sensible resistance when forcing our way through them. The webs are of a bright yellow colour, and we found them stretching from ten to twenty feet, that is including the great ropes which are generally fastened to some neighbouring tree or a clump of bambus, the reticulated portion being about five feet in diameter, in the centre of which the spider sits waiting for its prey, he is of a dark black hue with red about him, but at this distance of time, now three years, I cannot remember his exact appearance. I brought one down with me from the summit of the mountain Maruk, which is eleven hundred feet above the Ganges, and he measured six inches across the legs when set up. It was in the web of this very spider that I found the bird entangled, and the young spiders (about eight in number and entirely of a brick-red colour) feeding upon the carcass. The bird was much decomposed and enveloped in web, but the beak and feet being visible I sketched them, a copy of which sketch I enclose for your satisfaction. The bird is a *Nectarinia* apparently, and probably *N. asiatica*: it hung with his head downwards, his wings were closely pinioned to his sides by the entwined web, and was nearly in the centre of the web. The old spider which I secured was above the bird about a foot removed.

Had we not been a half-starved party, we should have bottled the bird, spider and young ones, but we were at the end of a five-days' roam amongst these steep hills, covered with wet grass, without beds or covering, in the height of the rainy season, so you may imagine our commissariat was at too low an ebb to afford brandy for such a purpose. This communication from Capt. Sherwill is the more interesting, since the total demolition of Madam Merian's account of a bird-eating spider in Surinam, by Mr. W. S. McLeay, in the 'Proceedings of Zoological Society,' 1834, p. The species would

## STILLINGIA SEBIFERA.

appear to be an *Epeira*, most probably undescribed, and remarkable for the "bright yellow colour" of its web.—*Beng. As. Soc. Jour. No. VI. of 1850.*

(2830) SPRENGER, A Medical Officer of the Bengal Army. A philologist, who has contributed much to illustrate Persian and Arabic literature.

(2831) SSIPAN DAGH. The mountain called the Ssipan Dagh rises to the height of 10,000 feet, and lies between lake Van and the Murad Tchai or Eastern Euphrates. The river there is crossed on a raft, supported on inflated skins. The mountain appears to rise abruptly from the plain and is covered with perpetual snow. On one occasion travellers were detained nearly four hours on the banks of the river, owing to the difficulty in getting their horses to swim across, and many persons were waiting with exemplary patience to be carried over on the raft, all which would be avoided if the paternal Government of the Sultan would repair the two broken arches of the bridge.

(2832) STAUNTONIA LATIFOLIA.

Ramkela

Gophla.

Fruit edible.

(2833) STERCULIA, A genus of the Bytneriaceæ family; one species in Africa, and another in India, *S. foetida* yields a tragacanth like gum. *S. guttata*, grows in Malabar, the bark of the younger parts of the tree gives very strong white faxen fibres, from which the Wynaad inhabitants fabricate a coarse cloth. The tree is felled when ten years old, cut into pieces, the bark stripped off and chopped, washed and dried in the sun and without further process it is fit for clothing. *S. villosa*, the "Oadal" of Assam, is a native of the mountainous countries east of Bengal. Bags are made of its bark, and its fibres are made into cords to bind wild Elephants with. The rope is very strong and lasting, and little injured with wet. Rope made from the inner layers of bark are finely pliable, and the outer fibres yield a coarse rope.—*Eng. Cyc.*

(2834) STERCULIA FÆTIDA.

Junglee Badam.

• Natives roast and eat the seeds.

(2835) STERCULIA VILLOSA.

Oodial.

Kurdula.

A strong rope is manufactured from the bark fibres.

(2836) STEREOSPERMUM, Pathree Marum. One species, a large tree, the wood of which used for building and making cases, is common in Wynaad.—*McIvor. M. E.*

(2837) STILLINGIA SEBIFERA grows luxuriantly in the Deyhra Doon and lower Himalayas, and in the Kohistan of the Punjab. There is an interesting paper on the *Stillingia Sebifera* by Dr. Macgowan in the 7th volume p. 164 of the Journal Horticultural Society of India. It flowers in June and during the rains

## STORMS OF DUST IN INDIA.

and its seeds are collected in December. It grows luxuriantly in the Dehra Dhoon and lower Himalayas and in the Kohistan of the Punjab. In addition to the tallow obtained from its seeds and used in making candles a black dye is obtained from its leaves.

(2838) STORMS OF DUST IN INDIA. One observer of Dust storms, has attended to them as far back as the hot weather of 1847, when he first went to Lahore, and the result is as follows:—Dust storms are caused by spiral columns of the electric fluid passing from the atmosphere to the earth; they have an onward motion—a revolving motion, like revolving storms at sea—and a peculiar spiral motion from above downwards, like a corkscrew. It seems probable that in an extensive dust-storm there are many of these columns moving on together in the same direction, and during the continuance of the storm, many sudden gusts take place at intervals, during which time the electric tension is at its maximum. These storms hereabouts mostly commence from the north-west or west and in the course of an hour, more or less, they have nearly completed the circle, and have passed onwards.

Precisely the same phenomena, in kind, are observable in all cases of dust-storms: from the one of a few inches in diameter to those that extend for fifty miles and upwards, the phenomena are identical.

It is a curious fact that some of the smaller dust-storms occasionally seen in extensive and arid plains, both in the country and in Affghanistan above the Bolan Pass, called in familiar language "Devils," are either stationary for a long time, that is upwards of an hour, or nearly so; and during the whole of this time the dust and minute bodies on the ground are kept whirling above into the air, in other cases these small dust-storms are seen slowly advancing, and when numerous, usually proceed in the same direction. Birds, kites and vultures, are often seen soaring high up just above these spots, apparently following the direction of the column, as if enjoying it. [Note. They may be looking for prey, or involved in and unable to fly out of, the invisible part of the electrified aerial column, of which the lower part only is visible to us by the dust raised.—*Ed. Journal.*] My idea is that the phenomena connected with dust-storms are identical with those present in waterspouts and white squalls at sea, and revolving storms and tornadoes of all kinds; and that they originate from the same cause, viz. moving columns of electricity.

In 1847, at Lahore, being desirous of ascertaining the nature of dust-storms, I projected into the air an insulated copper wire on a bamboo on the top of my house, and brought the wire into my room, and connected it with a gold leaf electrometer and a detached wire communicating with the earth. A day or two after, during the

## STRIX.

of observing the electric fluid passing in vivid sparks from one wire to another, and of course strongly affecting the electrometer. The thing was now explained; and since then I have by the same means observed at least sixty dust-storms of various sizes, all presenting the same phenomena in kind.

I have commonly observed that, towards the close of a storm of this kind, a fall of rain suddenly takes place, and instantly the stream of electricity ceases, or is much diminished, and when it continues, it seems only on occasions, when the storm is severe and continues for some time after. The barometer steadily rises throughout. In this part of the world, the fluctuation of the barometric column is very slight, seldom more than two or three tenths of an inch at a time.

The average height at Lahore is 1180, corrected for temperature, indicating, I suppose, above 1150 feet above the level of the sea, taking 30 inches as the standard.

A large dust-storm is usually preceded by certain peculiarities in the dew-point, and the manner in which the particles of dew are deposited on the bulb of a thermometer. My mode of taking the dew-point is to plunge a common thermometer in a little ice, let it run down 20° or 30°.

The manner in which the electricity acts upon the dust and light bodies it meets with in its passage, is simple enough. I suppose the particles similarly electrified and mutually repulsive, and then, together with the whirling motion communicated to them, are whisked into the air.

The same takes place when the electricity moves over water. The surface of the water becomes exposed to the electric agency, and its particles, rendered mutually repulsive, are in the same way whirled into the air.

At sea the waterspout is thus formed. First of all is seen the cloud descending and beneath may be observed the water in a cone.—*Beng. As. Soc. Jour. No. V. of 1850 p. 790.*

(2839) STRIX. The Owl. Many races, alike of Europe and of Asia, continue to entertain superstitious opinions regarding species of this nocturnal genus. The women of India, hearing the hooting of the Ghugu, shut to them ominous sounds out from their ears by wrapping their Sarhis round their heads. Of the *Barn owl*, *Strix flammea*, a poet says:

The white owl seeks the antique ruined wall,  
Fearless of rapine; or in hollow trees,  
Which age has cavered, safely courts repose.

And Shakespeare notices the common superstition, when he says:—

It was the owl that shrieked, the fatal bellman,  
Which gives the stern'st good night."

*The Snowy owl, Strix nuctea*, has also been

When day declining sheds a milder gleam,  
 What time the May fly haunts the pool or stream;  
 When the still owl skims round the grassy mead  
 What time the timorous hare limps forth to feed;  
 Then be the time to steal adown the dale,  
 And listen to the vagrant cuckoo's tale;  
 To hear the clamorous curlew call his mate,  
 Or the soft quail his tender pain relate;  
 To see the swallow sweep the darkening plain  
 Belated, to support her infant train;  
 To mark the swift in rapid giddy ring,  
 Dash round the steeple unsubdued of wing:  
 Amusive birds! say where your hid retreat,  
 When the frost rages and the tempests beat;  
 Whence your return, by such nice instinct led,  
 When spring soft season lifts her blooming head?  
 Such baffled searches mock man's prying pride,  
 The God of Nature is your secret guide!  
 While deepening shades obscure the face of day,  
 To yonder bench leaf-sheltered let us stray,  
 Till blended objects fail the swimming sight,  
 And all the fading landscape sinks in night;  
 To hear the drowsy dore come brushing by  
 With buzzing wing, or the shrill cricket cry;  
 To see the feeding bat glance through the wood;  
 To catch the distant falling of the flood;  
 While o'er the cliff th' awakened churn owl hung,  
 Through the still gloom protracts his chattering  
 song;  
 While high in air, and poised upon his wings  
 Unseen, the soft enamoured wood lark sings;  
 These, Nature's works, the curious mind employ,  
 Inspire a soothing melancholy joy;  
 As fancy warms, a pleasing kind of pain  
 Steals o'er the cheek, and trills the creeping vein:  
 Each rural sight, each sound, each smell, com-  
 bine;  
 The tinkling sheep-bell, or the breath of kine:  
 The new mown hay that scents the swelling  
 breeze,  
 Or cottage chimney smoking through the trees,  
 The chilling night dews fall;—away, retire?"

White.

(2840) SULU. [From a paper by Mr. Bartlett, Cor. Secretary of the American Ethnological Society, in the Transactions of the Society.]

Mr. Itier, attache to the French mission in China, has recently visited a cluster of islands lying to the northeast of Borneo, between that island and Mindano. His researches on the natural history and geology of these islands, are of much interest. The soil is exceedingly fertile, and the climate more healthy than is usual in intertropical climates. The sugarcane, cocoa, rice, cotton, the bread fruit, indigo, and spices of all kinds, are among their products. Fruits and vegetables are of a great variety, abundant, and of a superior quality. Nine-tenths of the soil is still covered with the primitive forest, of which teak-wood, so valuable in ship building, forms a part. A considerable commerce with China and Manila is carried on, and from ten to

twelve thousand Chinese annually visit the island of Basilan, the most northerly of the group, to cultivate its soil, and take away its products. The peculiar situation of these islands, and their contiguity to the Philippines, to Celebes, Borneo, Manila, China, and Singapore, make them well adapted for a European colony. In fact, there do not appear to be any islands of the East Indies of equal importance, and there can be no doubt that with the present desire manifested by European nations for colonizing, this desirable spot will ere long be secured by one of them. The Sulu group embraces sixty inhabited islands, governed by a Sultan, residing at Soug. One of these would be an advantageous point for an American colony or station.—*Jour. of the Indi. Arch. Vol. No. 7 July, 1849, page 412.*

(2841) SUNJIE UJONG :—a state, in the interior of Malacca.—*Benl. As. Soc. Jour. No. IV. of 1856. p 366.*

(2842) SUNG YANG HILLS, of China bordering on Fohkien.

"*Alum.*—About eleven hundred tons of Alum have been exported from Ningpo within a short period, chiefly to India. This mineral is largely employed by the Chinese in dyeing, and to some extent in paper-making as with us. Surgeons apply it variously after depriving it of its water of crystallization, and in domestic life it is used for precipitating vegetable substances suspended in potable water. It is used also by the Chinese in a manner peculiar to themselves. Fishermen are usually provided with it, and when they take one of those huge *Rhizostoma* which abound on the coast they rub the animal with the pulverized styptic to give a degree of coherence to the gelatinous mass. Architects employ it as a cement in those airy bridges which span the water-courses. It is poured in a molten state into the interstices of stone, and in structures not exposed to constant moisture the cohesion is perfect, but in damp situations it becomes a hydrate and crumbles, a fact of which the whole empire was officially informed by the government about thirty years ago. It was discovered that water had percolated into the mausoleum of Kiaking, having been built too near to the mountain side, the alum cement imbibed moisture, segregated and opened the way for to enter the tomb. In those peaceful days such an event was of such importance as to call forth edicts and rescripts, memorials and reports in succession for several months. The son-in-law of the deceased monarch to whose care the construction of the edifice had been entrusted was fined and degraded, and a statesman from Fohkien acquainted with the properties of alum was appointed to remove it a short distance from the mountain.

"Alum was first introduced into China from the West, and until a comparatively recent period the best kind called sometimes Persian, and at others Roman Alum was brought from Western

## SUNG YANG HILLS.

**Asia.** Numerous localities where an inferior article is manufactured are mentioned in the *Pharmacopœia*—viz., Shan-tung, Shan-se, Kiaug-su, Hukwang, Sz'-chuen, also in the South-western frontier and in Tibet. That from Sz'-chuen is represented as having the property of converting iron into copper or of coating iron with copper, by placing the former metal in a solution of rice liquor and alum, the stone of that province. The most recent editions of works on materia medica contain no reference to the mines in this province, the products of which have surpassed in quality the foreign, and rendered its importation unnecessary. From this and from other circumstances it is certain that the works which we shall now describe have not been long in operation. They are in the Sung-yang hills bordering on Fohkien in the district of Ping-yang, Wan-chan prefecture, and in close proximity to Pehkwan harbour ( $27^{\circ} 9' 10''$  N.,  $120^{\circ} 32' 6''$  E.)

The locality has been visited by one foreigner only, to whom we are indebted for most of the following particulars. About two months ago, he started from Chih-k'-i bight in Lannai harbour to which Ningpo boats resort for this commodity to the Northward of Peh-kwan. Three hours' hard walking over a succession of precipitous hills crossed by stone steps and pathways brought him to the mines. Ten Alum-making establishments were in operation, which, with the exception of one on a hill opposite, occupied about a mile of the side of a lofty hill. The works were adjacent to the quarries from which the Alum-stone seemed to crop out of decomposed rock of the same lithological character. The stones were thrown into a fire of brushwood where they burnt with a slight lambent flame and as they cracked, the fragments were raked out broken into small pieces, and macerated in vats. Subsequently the disintegrated mineral was thrown with water into a vessel having an iron bottom and sides of wood and boiled for a short time. The lixivium was then poured into large reservoirs where it crystallized into a solid mass. Blocks of alum weighing about fifty catties each were hewn out of the reservoir and carried in this state in bamboo frames, one on each end of a porter's pole to the place of shipment, where it is broken into fragments. When not designed for immediate exportation, the blocks are stored away for drying. On reaching the depot the alum is found charged with a double quantity of moisture, the porters being obliged to deliver a certain weight, they dip their burdens in the mountain streams which they pass in the journey. Judging from the number of labourers engaged in transporting the mineral on the day of our informant's visit, the quantity brought from the works could not be less than eighteen tons. This was represented as less than an average day's work, and labour was in such demand just then

## SUMATRA.

for agricultural purposes that double pay was given and aged men, and women, with boys and girls were pressed into the service. Assuming that day's product as a basis for calculation and making an allowance for rainy days, we may safely estimate the annual supply as between five and six thousand tons. The quantity consumed by the dyers of Ningpo prefecture alone, being nearly twenty-two tons per annum, is corroborative of this estimate. The supply is literally inexhaustible. Five dollars-and-quarter a ton at the landing would afford the manufacturer a fair profit. It often fetches much more, as there has been an increasing demand for the article owing to the greater facilities afforded for exportation from Ningpo in foreign vessels.

The Wan-chau Alum is equal to the best Roman,—a roseate tint in some specimens indicates the presence of minute quantities of iron.

We have no means of ascertaining the precise geological position of the rock from which this alum is procured; some circumstances seem to indicate it to be a new mineral. It is stated that no potash nor any other material is employed in the works. Granitic and porphyritic rocks abound in the vicinity, and some parts of the district produce iron and silver. According to the Wan-chau Topography, the working of silver was discontinued in the reign of Wan-lih (1615) in consequence of imperial prohibition. This part of the coast has recently become the seat of extensive poppy cultivation for the bane of the Chinese race.

As a contribution to the physical description of the alum district, we would add that the typhoon of September 1855, was preceded by a rising of water in wells and ponds many miles inland. When the cyclone reached the coast it submerged about a hundred square miles, occasioning a vast destruction of life and property. The waters of the sea were retained in the country by strong Easterly winds for several days leaving a strip of land bordering on the sea quite dry."—*North China Herald*, 23rd January 1856."

The rock, for it is one, and not a mineral, is a gray felspar porphyry with minute brilliant white specks, which may be arsenical pyrites, silvery mica or sulphuret of nickel, but I was unable to sacrifice enough of the rock to ascertain what it was. When polished it shews a very pretty surface, and a small portion pulverised and calcined and then boiled gave sulphuric acid and alumina to the usual tests, so that it is probably an alum porphyry, i. e. a porphyry containing Alunité.

(2843) SULPHATES OF SODA. KHARIN-NOON, effloresce on the soil of Tirhoot and Sarun in the province of Behar.

(2844) SUMATRA. *Position and Extent.* Leaving out of view its modern alluvial accessions,

## SUMATRA.

Sumatra consists of a rectilinear belt of elevation, stretching from the parallel of Pinang to that of Bantam, and shutting in the Malay Peninsula and China Sea from the Indian Ocean. Its extreme northwest and southwest points differ  $10^{\circ}30'$  in longitude and  $11^{\circ}40'$  in latitude, the former being in  $5^{\circ}45'$  N. B.,  $95^{\circ}10'$  E. Long. and the latter in  $5^{\circ}55'$  S. L.,  $105^{\circ}40'$  E. Long. The belt thus makes an angle of about  $36^{\circ}$  with the meridian, its direction being a little west of N. W. by N., which gives it a length of about 925 geographical miles. Its average breadth appears to be rather more than 90 miles, as it nowhere expands to a much greater breadth for a considerable space save in the middle region, nor contracts to a less save at the northern and southern extremities. The area covered by it is about 85,000 square miles. The true limits and configuration of this mountain region on the east have not been ascertained, but it probably forms a vast number of systems of low hills as on the west coast, and as in the Malay Peninsula on the margins and in the depressions of the belt of mountain groups. The body of the Sumatran zone does not appear to consist of elevated chains of great length, but of numerous short ranges and isolated mountains varying extremely in all their dimensions. The circumstance of the belt being partly plutonic and partly volcanic forms its peculiar character. Its configuration is in fact a combination of that of the Malay Peninsula with that of Java, with this difference that its middle region is more elevated and expanded than any part of the peninsula, several of its masses being about thrice the height of the highest summits of that range. If a number of volcanic mountains rose here and there amongst the peninsular groups, and in greatest number in Pera, Tianggau and Patani, where it is broadest, it would be identified in character with Sumatra. The greater elevation of the mountains of the latter is however accompanied by a greater expansion of the plains and vallies which lie amongst them. In crossing it anywhere, save towards its northern and southern extremities, three, and sometimes more, principal ranges are found with wide table lands, plains or vallies between them, watered by numerous streams, and in some places containing lakes, as in the principal Korinchi plain, the great Malayan plain of Menanghabau and the Bata plain of Tobah. The most western ranges form the water shed, and as the land to the west of it, chiefly hills, is not more than 25 miles broad, about one fifth only of the waters of the island fall into the Indian ocean, the Straits of Malacca and the Java sea receiving the remainder, in nearly equal proportions as regards the drainage of the mountains, but with a large excess to the latter from the wide plain traversed by the rivers that disembogue into it.

The western margin of the belt, washed by

## SUMATRA.

the strong waves of the Indian Ocean, has retrograded to the eastward, the sediment of the rivers and the debris of the coast being carried away instead of being deposited. The northern part of the east coast, exposed to the assault of the Bay of Bengal, has retained its ancient dimensions, if it has not contracted, but as soon as the open sea is exchanged for the Straits of Malacca, the mountain belt begins to retire from the coast, and a great alluvial plain commences, which, to the south of the S. E. extremity of the Batta country opposite Parcelar hill, where the Peninsular and Sumatran belts approach nearest each other, expands to a breadth varying from 60 to 110 miles. The length is about 600 miles and the average breadth about 70 miles which gives a surface of about 42,000 square miles. [Note. This plain and the mode of its formation, was described in a Sketch of the Physical Geography and Geology of the Malay Peninsula, Journ. Ind. Arch. Vol. II. p. 129-132.] If to this we add 1,500 square miles for the area of the flat alluvial land to the north of [the great plain, we shall have 128,500 miles as the area of the whole island, [Note. This result is nearly identical with the gross estimate of Lieut. Melville vanCarnbee, which is 8,035 leagues = 128,560 Eng. sq. geo. miles. ib. p. 176.] the mountain region occupying about two thirds. The islands on the west coast give a further surface of 5,000 miles to be added to the elevated region, and this will make it almost exactly double the size of the alluvium.

### *Range and numbers of the different Races of Inhabitants.*

#### I. Wild Tribes.

There are two races which, not being confined to particular localities, it is necessary to mention first. They are at the opposite extremes of the civilization of the island. The one is a half wild people, the scattered remnants of the aboriginal inhabitants, now broken by oppression and solitary confinement for centuries in the jungly mountains, into a number of disconnected patches of communities, differing, it is probable, considerably in language and little in condition and ideas. Most of the notices of them are so meagre that they do nothing more than prove the fact of their existence in widely separated parts of Sumatra. Thus in the north, where they are known under the name of Orang Lubu the Battas describe them as having inhabited Pertibi before they occupied it. [Note Willer, Tigd. v. N. Ind. 8th y. 2d part p. 402.] They are found up the Mandan above Siak [J. Anderson, Mission to Sumatra p. 349.] In the south again they are mentioned under the name of Orang Kubu by Marsden and other writers who resided on the west coast, and we know from information received from Malays that they are found in the interior on ascending most of the large rivers whose embouchures are on the east coast. Major Sturler in his account of Palembang

bang gives a particular description of the Orang Kubu, who in condition and habits entirely agree with the wilder tribes of the Malay Peninsula. The same remark applies to the Orang Gunong of Banka. The southern extremity of the mountain belt is inhabited by the Orang Abung, a head hunting race. These are the mountain nomades, but there are also half wild people, some living in boats in the salt water creeks, and others in the sago forests and low jungles of the east coast. In this lowest class of Sumatran tribes should be included those inhabiting some of the western islands, such as the Enganoans.

Their physical resemblance to the Malays is everywhere remarked, and, as formerly stated, in the Journ Ind. Arch. Vol. II. p p 332, 517, there seems no room to doubt that they are the aborigines of the Malayan region of Sumatra, and the remnants of the stock from which the present Malays have descended. Their numbers may be provisionally assumed at 6,000. The Abung and Kubu in the south appear to near about 2,000.

## II. Orang Malayu (Malays.)

We now proceed to the Malay races themselves, the principal inhabitants of the island, whether we consider their range, numbers, actual territory, influence or civilization. They entirely occupy the wildest and middle region of Sumatra extending from the Rakan nearly to the Palembang on the east coast, and from Ayer Bangis to Kataun on the west coast, a length of about 275 m. with an average breadth of about 190 m. and a superficies of 52,250 square miles, or little short of one half of Sumatra. The east coast is nearly straight, running throughout in a direction due N. W. by N. and evincing the wonderful regularity, unity and power of the elevatory movement which formed the mountains. The breadth of the highlands is about 95 miles. The low land that stretches from their base to the east coast has about the same average breadth, so that the region is divided in nearly equal proportions between them. The greater part of the low lands appear to be nothing more than the waste matter of the mountains brought down by the streams, and as the ranges must have been pared down to a still greater proportionate extent on the western side of the watershed, where their sea face is exposed to a tremendous surf, the loss must have been enormous and the date of their elevation extremely remote. It is this accumulation of sediment over so wide a surface on the east side of the mountains that has given rise to the great rivers which intersect the plain, the Siak, Kampar, Indragiri, Iambi and Palembang. It was the possession of this central, largest and most highly favoured region, that enabled the Malays to grow in numbers and civilization till they obtained supremacy in Sumatra. The mountains contain numerous vallies, some

cleared by volcanic soil. The population varies extremely in density. The higher parts of the mountains, and the low land between the rivers, are left to the jungle and wild animals, and possess hardly any human inhabitants. The rivers have considerable collections of houses scattered at greater or less intervals along their banks, and extending a short distance from them. The principal vallies in the mountains, on the other hand, are completely cultivated and filled with inhabitants. While the countries of Siak, Indragiri, Iambi and the northern part of Palembang, including a portion about 25 miles broad of the eastern flanks of the mountain land, contain about 200,000 souls or 5 to the square mile, the single province of Menangkabau has a population of about 385,000 or 128 to the square mile, and the whole mountain land taken together gives a mean of 40 to the square mile.

The population is distributed as follows :

### 1st.—Malays of the Mountain region.

- a. Menangkabau.
- b. Malays of the Region of Sapulo Bua Bandar and Gunong Sungèi Pagu.
- c. The Korinchi.
- d. The Rawa.

### 2d.—The Malays of the hilly territories to the west of the mountain region.

- a. The sea-bord of Menangkabau (1700 sq. m.)
- b. The sea-bord of Sapulo Bua Bandar having a surface of 1,300 sq. m.

### 3rd.—The Malays of the low lands or eastern countries.

### 4th.—The Malays of the East Coast of the northern region.

Their entire number does not appear to be above 60,000, [Note. Anderson gives 350,000 as the population of this part of the east coast, but he includes a considerable portion of the Bata region lying behind the Malayan sea-bord, and it is clear that this number was a mere guess made without reference to the data of which he was in possession, for the numbers which he set down at the different places which he visited do not give an aggregate of much more than one half of this estimate, distributed as follows :

#### • Southern Races.

- III. Orang Palembang.
- IV. Orang Rejang.
- V. Orang Serawi.

## SUMATRA.

### The Northern Races.

#### VII. Orang Batta.

1st. Battas on the West Coast formerly subject to Malay rulers.

2nd. Battas on the low land and hilly region on the east side of the mountains.

3rd. Battas of the mountain region.

#### VIII. Orang Ache.

Western Islands.

IX. Orang Engano.

X. Orang Mantawei.

XI. Orang Niha or Nias.

XII. Orang Maruwi.

It will be borne in mind that the above estimates are for the most part rough approximations. The precise boundaries between the different races have nowhere been well ascertained and are doubtless in no case so regular as we have assumed for the purpose of calculation, but we believe the relative extent of country occupied by each will be found not to vary much from what we have allowed. It should also be remarked that not only do these races blend with each other at their boundaries, many districts and villages in the northern region for instance being peopled by Malays and Battas. Malays and Achinese, or Achinese and Battas, but most of the settlements near the coast possess in addition a very mixed population of foreigners from the rest of the Archipelago, China, India and Arabia, while Europeans are found in small numbers in the Netherlands possessions, chiefly at Palembang, Bankaulu and Padang. Our result of little more than two millions for the entire population is about one half of the current estimates. The most careful of these, that of Mr. Francis, is 4,500,000, \* but ours is to a large extent founded on the data supplied by him and his error consists in his having exaggerated the population of the countries for which he had no data. In the great majority of cases the effect of more careful enquiry has hitherto been to reduce general estimates for particular localities, and we may therefore believe that the gross population is under rather than above two million.

* Malays.....	2,000,000
Rejangs and Pasumahs...	600,000
Lampongs.....	150,000
Battas.....	1,200,000
Achinese.....	600,000

## SUMMARY OF NAIR LIFE.

### (2845) SUMMARY OF NAIR LIFE.

"The Nairs marry before they are ten years of age, but the husband never afterwards cohabits with his wife. Such a circumstance, indeed would be considered as very indecent. He allows her oil clothing, ornaments, and food; but she lives in her mother's house, after her parent's death, with her brothers, and cohabits with any person that she chooses of an equal or higher rank than her own. If detected in bestowing her favours on any low man, she becomes an outcast. It is no kind of reflection on a woman's character to say, that she has formed the closest intimacy with many persons; on the contrary, the Nair women are proud of rec-

## SWALLOW.

In consequence of this strange manner of propagating the species, no Nair knows his father; and every man looks upon his sister's children as his heirs. He, indeed, looks upon them with the same fondness that fathers in other parts of the world have for their own children; and he would be considered as an unnatural monster, were he to show such signs of grief at the death of a child, which, from long cohabitation and love with his mother, he might suppose to be his own, as he did at the death of a child of his sister. A man's mother manages his family, and after her death his eldest sister assumes the direction. Brothers almost always live under the same roof; but, if one of the family separates from the rest, he is always accompanied by his favourite sister. Even cousins, to the most remote degree of kindred, in the female line, generally live together in great harmony; for in this part of the country, love, jealousy, or distrust, never can disturb the peace of a Nair family. A man's moveable property, after his death, is divided equally among the sons and daughters of all his sisters. His land estate is managed by the eldest male of the family; but each individual has a right to a share of the income. In case of the eldest male being unable, from infirmity or incapacity, to manage the affairs of the family, the next in rank does it in the name of his senior."—*Buchanan Hamilton, quoted in Journ. of the Ind. Arch. Vol. III. No. VI. June 1849, p. 364.*

(2846) SUSUP, the Malay name of a tree having a bright scarlet flower, found on the island of Pulo chiku koh.

(2847) SUTWASA, a rite observed amongst Mahomedans when a woman has attained the seventh month of her pregnancy.—*Herk.*

(2848) SWALLOW. The chimney swallow *Hirundo rustica*, of Europe, has been thus addressed.

Welcome, welcome, feather'd stranger,  
How the sun bids nature smile;  
Safe arrived, and free from danger,  
Welcome to our blooming isle;  
Still twitter on my lonely roof,  
And hail me at the dawn of day,  
Each morn the recollected proof  
Of time that ever fleets away.

"Fond of sunshine, fond of shade,  
Fond of skies serene and clear;  
E'en transient storms thy joy invade,  
In fairest seasons of the years.  
What makes thee seek a milder clime?  
What bids thee shun the wintry gale?  
How know'st thou thy departing time?  
Hail! wondrous bird! hail, swallow, hail!

## SYKES, COLONEL.

Sure something more to thee is given,  
Than myriads of the feather'd race,  
Some gift divine, some spark from heaven,  
That guides thy flight from place to place.  
Still freely come, still freely go,  
And blessings crown thy vigorous wing;  
May thy rude flight meet no rude foe,  
Delightful messenger of spring!"

(2849) SWORD BLADES OF CUTCH. An inch bar of fine English or Swedish steel is forged into plates 7 inches long, 1 broad and  $\frac{1}{8}$  thick: similar bars of fine spot iron are prepared in the same manner. These are smeared with a paste of borax dissolved in water, and laid in piles of twelve, nine of steel to three of iron, or three to one, alternately; each pile is wrapped round with rag thickly plastered with mud made of a loamy earth; then heated, welded, and drawn out to a bar one inch and one eighth broad and one third of an inch thick, this is bent zigzag three or four times; is again welded and drawn out to half an inch thick; and during the heat, borax is frequently dropped on the metal while in the fire. Two of these bars are next welded into one and when about twelve or fourteen inches long it is bent into the form of a loop or staple. In the middle of this a piece of fine grained file is inserted of the same width and nearly as thick. All is then welded together and the blade is formed.

*Tempering.*—An earthen pot twelve inches wide and six deep is notched on the edges (the notches being opposite each other) with a file about a quarter of an inch deep and is then filled nearly up to the notches with water. Oil is then poured on the surface. The blade being heated equally to a light red is removed from the fire and the point entered into a notch on one edge is passed to the opposite one keeping the edge from a quarter to half an inch in the oil. It is drawn backwards and forwards rather slowly till the hissing ceases and the rest of the blade above the fluid has become black. A jug of water without oil is then poured along the blade from heel to point. In order to take out the warp produced by tempering, the blade when nearly cold is passed over the fire three or four times, then being brought to the anvil is set straight by striking it regularly but moderately with a hammer; by this means a damascus curved blade may be brought nearly straight.—*Rohde, M.S.S.*

(2850) SYEDANI, HIND. A Syed woman.

(2851) SYKES, Colonel W. H. An officer of the Bombay Army, a statistician, zoologist and statesman.

## T.

(2852) TABASHEER, CHEMICAL ANALYSES OF, BY THOMAS THOMPSON, M.D., &c.

Tabasheer is a concretion met with occasionally in the joints of the bamboo; it has been long employed in medicine, in Hindoostan and the east; it is very much esteemed; and sells at a considerable price. The first good description of it was drawn up by Dr. Russell, and published in the "*Philosophical Transactions*," for 1790, p. 273. The specimen, laid before the Royal Society, by Dr. Russell, was put into the hands of Mr. Smithson for chemical examination. A very minute, accurate, and complete set of experiments, by this acute and accomplished philosopher, was published in the "*Philosophical Transactions*," for 1791, p. 368, from which it appeared, that the tabasheer was composed of silica nearly in a state of purity.

In the year 1806, a specimen of tabasheer, from Peru, was put into the hands of Fourcroy and Vanquelin, by Humboldt and Bonpland. These chemists subjected it to analysis, extracted from it 70 per cent. of silica, together with a little lime, and concluded though it is not easy to see the evidence, that the tabasheer, which they examined, was a compound of 70 parts of silica, and 30 parts of potash. But under the potash were included the vegetable matter which they showed it to contain, and also, the water, the amount of which, they seem not to have thought of determining.

In 1819, a curious paper on the optical properties of tabasheer, was published in the "*Philosophical Transactions*," by Dr. Brewster. An abstract of this paper, together with several particulars, relative to the history and formation of the tabasheer, was inserted in the 8th Volume of Dr. Brewster's "*Journal of Science*," and in the same volume, we have a chemical examination of the tabasheer, by Dr. Turner. This analysis agrees very nearly with that of Mr. Smithson, and renders the accuracy of the statement of the great quantity of potash, announced by Fourcroy and Vanquelin, rather doubtful.

The tabasheer Dr. Thompson continues, which I examined, was a very beautiful looking substance, in small irregular fragments of a blueish white colour and pearly lustre, not unlike chalcodony in appearance, but much softer. For it was incapable of scratching calcareous spar, and only slightly scratched sulphate of lime. When put into water, it gives out a great deal of air with a kind of crackling noise, and imbibes a great deal of water.

I found its specific gravity, (taken without

allowing time for the internal air to escape), 1.9138. But, when by means of heat all the air bubbles had been driven off, the specific gravity was as high as 2.0824.

When ignited, it lost 4.87 per cent. of its weight. This loss consisted chiefly of water, but not entirely, for the tabasheer exhaled a peculiar odour, and showed evidently, the existence of a small quantity of vegetable matter in it.

Ten grains of tabasheer reduced to a fine powder were digested in distilled water for 24 hours. The water when concentrated was tasteless; but slightly reddened vegetable blues. Being evaporated to dryness, grayish scales remained, weighing 0.6 gr. These scales being digested in muriatic acid, a little iron was dissolved, but the scales consisted almost entirely of silica. Thus it appears that the silica in the tabasheer is still soluble in water. I am disposed to consider, the reddening of vegetable blues in this case, as produced by the dissolved silica; at least, I did not succeed in finding any trace of any other acid substance. When the muriatic acid dissolved upon the scales was evaporated to dryness, a brown matter remained, which besides iron, contained also a trace of vegetable matter, but too small to admit of examination. It contained also a little lime and a little silica.

Ten grains of tabasheer reduced to a fine powder were mixed with 24 grains of finely pounded flour spar, and the whole was made into a thin magma by means of sulphuric acid. This mixture was exposed for some hours to the heat of the sand bath in a platinum crucible. After the exhalations of fluo-silicic acid had ceased, the crucible was exposed to a heat gradually increased to redness, and kept in that temperature till all the excess of sulphuric acid had been driven off. The white matter in the crucible (chiefly of lime) was now lixiviated with water, till every thing soluble was taken up. The water thus employed, was mixed with some carbonate of ammonia, and filtered to separate the lime which it had dissolved in the state of sulphate. The water, thus nearly freed from lime, was reduced to a small quantity, by evaporation, and while still hot, was mixed with a few drops of solution of oxalate of ammonia, to throw down a little lime which had either escaped the action of the carbonate of ammonia, or had been afterwards supplied by the filter. The mixture was allowed to stand till it became clear, the liquid was then drawn off

## TABASHEER.

with a sucker, evaporated to dryness, and the saline residue exposed to a red heat. A salt remained, which weighed 0.2 grains, and which proved, on examination, to be sulphate of potash, equivalent to 0.11 grain potash.

Ten grains of tabasheer in the state of a fine powder were intimately mixed with 20 grains of anhydrous carbonate of soda, and the mixture exposed in a platinum crucible to red heat, raised at last sufficiently high to bring the whole into a state of fusion. The colour of the fused mass was yellowish brown. It was dissolved in muriatic acid, the solution evaporated to dryness, and the residue, after being digested a sufficient time in muriatic acid, was thrown on the filter. The silicaedulcorated, dried and ignited weighed 9 grains.

The muriatic acid, in which the silica had been digested being concentrated, was mixed with caustic ammonia. Yellow flocks, fell, which were separated by decantation: these flocks, when ignited, became dark brown, and weighed 0.1 grain; they dissolved readily in muriatic acid. The solution was super-saturated with caustic potash, and digested in the sand bath for 24 hours. By this means 0.10 grains of alumina was dissolved. The rest consisted of peroxide of iron. Thus, the yellow flocks thrown down by caustic ammonia consisted of Peroxide of iron,..... 0.09

Alumina,..... 0.01

0.1

The liquid from which this precipitate had fallen was not rendered muddy by carbonate of ammonia. It was, therefore, evaporated to dryness. A greyish matter remained weighing 0.08 grain. This matter being digested in muriatic acid, there remained undissolved 0.05 grains of silica. The 0.03 grain dissolved, consisted of a mixture of alumina, and lime.

Thus, the constituents obtained were:—

Moisture.....	0.487	or	4.87
Silica.....	9.050	„	90.50
Potash.....	0.110	„	1.10
Peroxide of iron.....	0.090	„	0.90
Alumina.....	0.040	„	0.40

9.777 97.77

The loss, amounting to 2.23 per cent., was probably the consequence of my employing different portions of the tabasheer in different steps of the analysis. For they were not all exactly the same in appearance. Hence, possibly the proportion of the constituents might vary somewhat in each. But my supply of tabasheer was not sufficiently great to admit of a new analysis upon a large scale. I did not weigh the lime; but do not think it could exceed 0.1 per cent. It is needless to observe, that the preceding analysis, accords sufficiently with the experiments of Mr. Smithson and Dr. Turner, and there-

## TAKIN.

fore, serves to confirm them. The tabasheer examined by Smithson, Turner, and myself was from India; that subjected to examination by Fourcroy and Vauquelin was from South America. It remains to be seen whether the constitution of the American tabasheer be essentially distinct from the Indian, as would appear from the 30 per cent of alkali &c. found in it by Fourcroy and Vauquelin.—*Thompson's Records of General Science, Vol. III. p.p. 132-35.*

(2853) TABOOT OR TAZEEAH, ARAB. A bier in the shape of a mausoleum, intended to represent the one at Kurbulla erected over the remains of Hoossain. It consists of a bamboo frame work, the interstices being filled up with a nicely clipped net work of paper, often pasted on mica. Within it are placed Ullums, or tombs to represent those of Hussun and Hoossain, but every variety of materials is employed, from the purest silver, to ivory, ebony, sandal wood, cedar, down to bamboo.—*Herklots.*

(2854) TAGAL, dry rice cultivation [equivalent to the Malay muah.

(2855) TAGETES PATULA. *Gool Jafree.* Pers.—*Genda*, Beng.—(Roxb.) This grows in gardens at Bombay; worn by native women in their hair.—*Graham (Thomson's Records of Gen Science, Vol. IX. p. 303.)*

(2856) TA-GOUNG, the ancient capital of the Burmese Empire.

(2857) TAH-NOUNG, is a most beautiful, though rather small tree. Leaves very small, composite, lively green, rising from the base of a double thorn.—*V. I. p. 188.*

(2858) TAKIN. *On the Takin of the Eastern Himalaya: Budorcas Taxicolor.* Blyth in *Beng. As. Soc. Jour. No. I. of 1850, p. 65.*

This remarkable animal adds another and a highly characteristic species to the group, and, when it is stated that this animal has its abode in the Mishmi mountains, or, in other words, in the Eastern Himalaya, all persons conversant with the features and climate [J. A. S. No. 135, for December 1847, and No. 206, for August 1849.] of all that locality will readily acknowledge the interest attaching to the discovery in our moist umbrageous and precipitous mountains, of this large and striking quadruped.

The large, massive and remarkable animal, denominated Takin by the Mishmis, and Kin by the Khamtis, is one of the group of Bovine Antelopes. Its nearest affinity is probably to the Gnoos; but it has various points of stronger connexion with Musk Oxen, and in a natural system its place would probably be assigned between those two types. But before making further allusion to its affinities, I shall give a careful description of its appearance and structure, premising the account of them by a statement of what is known of its habitat and manners.

## TAKIN.

The Takin tenants the easternmost part of the Himalaya, or that which is adjacent to Yunan, Sechuen and Kham. In the Himalaya it is stated to belong more especially to the Upper or Alpine region, but to be found also in the central region, though never in the lower region, [Notes, See J. A. S. No. 206, Phys. Geog. of Himalaya,] and it probably extends its range from the Himalaya proper, to the proximate mountains of China and Tibet. The Takin derives its high interest for the naturalist, not merely from its compound structure, made up, as it were, of the Ox, the Antelope, the Sheep and Goat, but also from its habitat, so remote and dissimilar from those of its allies. The Takin is described as being an animal of high courage and great ferocity; so that it cannot be taken alive, and is killed by the natives with much trouble and some risk. It is said to be very gregarious, though old males are sometimes found solitary; but, for the most part, the species herd together in considerable numbers. Strength and ferocity are inscribed in very legible characters on the form and aspect of the Takin, which is a much larger as well as bulkier animal than the lusty Caprine Antelope (Thar) of the Himalaya. The Takin however reminds one in several respects of the Thar, [Schinz in his *Genera Mammalium* has actually ranged this animal with the Gnoos. This is a mistake, but one indicative of remote affinity. The Thar is a typical *Nemorhedus*,—See J. A. S. No. 181. for July 1847.] which it much resembles in colour as well as by its short Caprine tail, harsh adpressed hair, and vigorous make, suited to climbing these stupendous mountains. But the Thar is in structure as much more Antelopine as the Takin is more Bovine. The latter is not much, if at all, inferior in size or bulk to the female Yak; and, as seen from the front especially, with its lunate horns displayed and its short tail, concealed, it would be at once pronounced to belong to the Ox kind, close examination alone being likely to suggest any doubts on that head. The Takin, as I have said, is nearly as large, both in dimensions of extent and in bulk, as a female Yák; and its massive form and peculiar proportions are quite Bovine. It is in length, from snout to vent, six and a half feet; and in height, three and a half feet at the shoulder. Its head is 20 inches. Its ears 5 inches. Its tail 3 inches, or 8 with the hair. The head is large and heavy, the neck short and thick, the body somewhat elongated but deep in the barrel, and yet more so in the shoulder, which is said to be raised in the Bison-tine manner. The limbs are short, stout and Bovine, and so are the broad hoofs. In Takin there is no approach to the Cervine limbs, or equine body and tail of the Gnoos: and the horns of the Takin, which to a superficial view are round, smooth and lunate, would complete the impression of a Bovine animal, were not progres-

## TALAPOINS.

sive attention almost necessarily now turned to the short narrow pointed ears, very short depressed tail, and hairy attenuated muzzle of this animal; particulars in which, with others to be presently mentioned, the Takin deviates from the Bovine to approach the Ovine or Caprine type, and is sundered from the Gnoos in the same degree, that it is approximated to the Musk Oxen or Ovibos.

The head of the Takin is large, heavy and inelegant, exhibiting a mixed character, compounded of the Bovine and Ovine types. Its vertical dimensions (or height) are great, owing to the lofty curve of the nose and forehead, the chaffron being more romanised than even that of the Barwal (*Ovis Barual*). But the length also of the head of the Takin is considerable, and surpasses that of any Caprine or Ovine head, though inferior to the full normal length of head, characterising the Ox tribe. The head, though large and upon the whole perhaps Bovine, yet lacks the characteristic squareness of the Ox's head, both jaws being attenuated towards their aural extremities much more than in the Ox, though somewhat less than in the sheep and goat. There is in the muzzle of the Takin neither the nudity nor the breadth of that of the Ox and Gnoo, but on the contrary the lips are both tapered and clad with hair almost as much as in the goats and sheep, and the animal is consequently a browser not a grazer. Nevertheless the mere nostrils, which are wide and terminal, have a decidedly Bovine character both as to form and position; and, as it were to remind us of the true Bovine muzzle, there is a clear broad margin round the nostril which is quite nude and moist.—*Beng. As. Soc. Jour. No 1 of 1850.*

(2859) TALAPOINS. According to the tenets of this religious order of Buddhist Monks, there exists an eternal law, which when obliterated from the memory of men, can be known again, and, as it were, recovered and only thoroughly understood, by the incomparable genius and matchless wisdom of certain extraordinary personages called Budhs, who appear successively and at long intervals during the various series or successions of worlds. These Budhs or Budhas announce that law to all the then existing rational beings. The great object of that doctrine is to point out to them the means of freeing themselves from the influence of passions, of becoming abstracted from all that exists; that being thereby delivered from the action of evil influence, which causes mortals to turn incessantly in the whirlpool of never ending existence, they may obtain the state of Neiban or rest, that is to say, a situation wherein the soul, disentangled from all that exists, alone with herself, indifferent to pains as well as to pleasures, folded, as it were, upon herself, remains for ever in an incomprehensible state of complete abstraction and absolute rest. A Budh is a being who, during

myriads of existences, slowly and gradually gravitates towards this centre of an imaginary perfection, by the practise of the highest virtues. Having attained thereto, he becomes, on a sudden, gifted with a boundless genius, wherewith he at once discovers the wretched state of all beings, and the means of delivering them from it. He thoroughly understands the eternal law which alone can lead mortals in the right way, and enable them to come out of this circle of existences, wherein they have been unceasingly turning and moving in a state of perpetual agitation opposite to that of fixity or rest. He preaches that law whereby man is taught the practice of those virtues which destroy gradually in him every evil influence, every affection for all that exists, and brings him at last to the end of existence, possession of Neiban. His task fulfilled, Budh dies, or rather to use the language of Budhists, he enters into the state of Neiban. In that situation which is truly inexplicable, he knows nothing of, and enters nowise into the affairs of this world. He is as if he was not, or had never been. Budhists venerate three precious things, Budha, his law, and the assembly of the just or perfect, in the same sense as we venerate and admire what is morally good and beautiful, such as virtue considered abstractedly and the acts originating from it. The statues of the last Budh, Gaudama, are honored by his followers, not with the idea that any powers or virtues are inherent in them, but solely because they are the visible representations of Budh, who desired that the same honor should be paid to them, as would be offered to his person, were he yet living among them. This faint outline of the Buddhistic creed is sufficient to bear out the above assertion, that it is in no wise based on the belief in a Supreme Being, but is strictly Atheistical, and therefore that no real priesthood can ever be found existing under such a system. It may prove too of some assistance for better understanding what is to be said regarding the subjects of this notice.

A Buddhist on becoming a member of this holy society, proposes to keep the law of Budh in a more perfect manner than his other co-religionists. He intends to observe not only its general ordinances obligating on every individual, but also its prescriptions of a higher excellency, leading to an uncommon sanctity and perfection, which can be the lot of but a comparatively small number of fervent and resolute persons. He aims at weakening within himself all the evil propensities that give origin and strength to the principle of demerits. By the practice and observance of the highest and sublimest precepts and counsels of the law, he establishes, confirms and consolidates in his own soul, the principle of merits, which is to work upon him during the various existences he has as yet to go through, and gradually lead him to that perfection which will qualify him for, and entitle him to the state

of Neiban, the object of the ardent desires and earnest pursuit of every true and genuine disciple of Budha. The life of the last Budha, Gaudama, his doctrines as well as his example, he proposes to copy with scrupulous fidelity and to follow with unremitting ardour. Such is the great model that he proposes to himself for imitation. Gaudama withdrew from the world, renounced its seducing pleasures and dazzling vanities, curbed his passions under the yoke of restraint, and strove to practise the highest virtues, particularly self-denial, in order to arrive at a state of complete indifference for all that is within or without self, which is, as it were, the threshold of Neiban.

Like the monk, the Talapoin bids a farewell to the world, wears a particular dress, leads a life of community, abstracts himself from all that gives strength to his passions, by embracing a state of voluntary poverty, and absolute renunciation of all sensual gratifications. He aims at obtaining by a stricter observance of the law's most sublime precepts, an uncommon degree of sanctity and perfection. All his time is regulated by the rules of his profession, and devoted to repeating certain formulas of prayers, reading the sacred scriptures, begging alms for his support &c. These features of exterior resemblance common to institutions of creeds so opposite to each other, have induced several writers little favourable to Christianity, to pronounce without further enquiry that Catholicism has borrowed from Buddhism many ceremonies, institutions and disciplinary regulations. Some of them have gone so far as to pretend to find in it the very origin of Christianity. They have however been ably confuted by Abee Remusat in his *Memoir intituled Chronological Researches into the Sanaic Hierarchy of Thibet*.

It is somewhat surprising to find in the middle of half civilized nations, such as the Burmese, Siamese, Cingalese, and Thibetans, a religious order with a distinct and well marked Hierarchy, constitution and regulations, providing for the admission of members, their occupations, duties, obligations and their mode of life, forming as it were, a compact, solid and perfect body, that has subsisted almost without change during several centuries, and survived the destructions of kingdoms, the fall of royal dynasties and all the confusion and agitation produced by political commotions and revolutions. It is in Thibet, that the order is found existing in the greatest perfection, under the fostering care of the Great Lama, or High Priest, who combines in his own person the regal as well as the sacerdotal dignity and power. In the city of Lassa, a Pontifical Court, an elective sacerdotal chief, and a college of superior Lamas, impart to the order, dignity, decency, respectability and stability, which insure its continued existence, and more or less extend its influence over its members living in distant

countries, ruled by a foreign sovereign. The period of the introduction of Buddhism from India into Thibet, is very uncertain, if not quite unknown, but it appears certain, that the establishment of a Pontifical chief or sovereign, with royal prerogatives, was set up by one of the grandsons of the great Tartar warrior Gengis in or about the middle of the thirteenth century. In other countries, where the order has no connection whatever with the civil power, we expect to see it surrounded with an equal splendour, or subsisting in the same state of perfection, regularity and fervour. Extraordinary indeed would be its vital energies, were the remotest parts of this great and far spread body to receive the same impulse and exhibit the same symptoms of vitality as those nearest to the heart or principle of life. Having never met with any detailed particulars regarding the Thibetan Monks, I must remain satisfied with laying before the reader, an account of all that relates to the constituent parts of the order, such as I have found them existing in Burmah, and developed in their sacred writings.

The whole fraternity is composed, 1st, of young men who have put on the Talapoinic dress, without being considered professed members thereof, or having hitherto passed through a certain ordeal somewhat resembling an ordination; they are called Shung: 2nd, of those who having lived for a while in the community, in a probationary state, are admitted professed members with the ceremonies usually observed on such occasions whereby the title and character of Talapoins are solemnly conferred—they are denominated Pazin: 3rd, of the heads of each house or community, who have the power to control all the inmates of the house: 4th, of a Provincial, whose jurisdiction extends over all the communities spread over the towns and villages of one Province or District: 5th, of a superior general, residing in the capital or its suburbs, called Haia Daw or great master, having the general management and direction of all the affairs of the order throughout the Empire. In the kingdom of Ava, the key-stone of the Talapoinic fabric is the superlatively great master residing in the capital or its suburbs. His jurisdiction extends over all the fraternity within the realm of his Burmese Majesty.—*Jour. of the Ind. Arch. Vol. IV. No. V and VI. May and June 1850, page 223.*

Talapoins, are known under different names in Ceylon, Siam, and Thibet, conveying nearly the same meaning, and expressing either the nature or the object of their profession.

This order of Buddhist Monks is known also as "Bonzes." The former word is derived from the Pali, "Talapat" meaning the leaf of a palm tree. These two words are used by the Siamese to designate the large fan made of palm leaves, set in a slender wooden frame, which Talapoins carry with them

when they go abroad. The votaries of Buddhism in Ceylon, Burmah, and Siam, Thibet, &c. show the greatest respect to the Talapoins. They are called by the Burmese Phonghis, which term means great glory, or Rabans which means perfect.

(2800) TALPA. The species of restricted *Talpa* that have hitherto been described amount to four only in number, viz. *T. europæa*, L., of Europe generally,—*T. cæca*, Savi, of Italy and Greece,—*T. moogura*, Temminck, of Japan,—and *T. microura*, Hodgson, of Nepal, Sikim, Butan, and the mountains of Asam: but the society's Museum has long possessed specimens of another from Cherra Punji, (N. of Sylhet), which I have recognised as distinct for some years, but now only proceed to describe.

In its external characters, the Cherra Punji Mole differs little from *T. microura*, except that the tail is considerably more developed, though much less so than in *T. europæa*; and the latter is clad and tufted with white hairs, whence I propose for the species the name of *T. leucura*. This animal, also, would seem hardly to attain the size of *T. microura*. An adult female in spirit measures  $4\frac{1}{2}$  inch long, with tail  $\frac{3}{8}$  inch additional: the latter is of a club shape, much constricted for the basal half. The general colour of the fur, too, is less fulvescent than is usual with *T. microura*. In both of these Asiatic species, as in *T. cæca*, there is no perforation of the integument over the eye, as in *T. europæa*; the skin being there merely attenuated and imperfectly transparent.

But the characteristic distinction of *T. leucura* consists in having only two small præmolars in the upper jaw anterior to the great last præmolar (*carnassiez*, or 'scissor-tooth'); both *T. europæa* and *T. microura* having three,—these being comparatively larger and less separated in the latter, and the *carnassiez* is also much larger in *T. microura* than in *T. europæa*. The posterior spur of the canine (? or pseudo-canine) [Note. In all the Insectivora, Cuv., which apparently possess upper canines, these teeth have rather the structure of *modified false molars*, and, I believe, have always double fangs, as exemplified by *Talpa*, *Centetes*, and *Gymrura*.] is remarkably developed in *T. leucura*, in place of the absent small præmolar. In the dentition of the lower jaw, there are also characteristic differences distinguishing these three species. In the Moles, as in most other Insectivora, and also in the *Lemuridæ* (the very peculiar genus *Cheiromys*, which has rodential tusks, excepted), the lower canine is minute and takes the form of an incisor, for which it has been very commonly mistaken; [Note. No placental mammal has more than three pairs of true incisors, or than three pairs of true molars (distinguished by their not being proceeded by deciduary teeth in the young animal, as is the case with all other teeth). Although certain in-

## TALPA.

stances occur, as especially in the hoofed ruminants, where the lower canine is hardly (if at all) to be distinguished from the incisors, yet this fourth supposed pair of incisors never co-exists with an undoubted canine (vide the Camels, Horses, Tapirs, &c.), that is among the *placental* mammalia, inasmuch as they are the veritable homologues of those teeth.] and the first præmolar is developed to assume the form of a canine, but locks *posteriorly* to the upper canine (or pseudo-canine, and like it has a double fang). There is no instance of a genuine lower canine locking behind the upper one, unless the gnawing tusks of the *Rodentia* and of the Lemuridous *Cheiromys* be regarded as the homologues of canines, which seems to be indicated more by the co-presence of undoubted upper incisors in the Leporidae, than the reverse is by the difficulty of always tracing the origin of upper rodentia tusks through the intermaxillaries to the true maxillary bones in the rodents generally. But to return to *Talpa leucura*: following the minute lower canine and the canine-like first lower præmolar of this species, there are two small præmolars anterior to the *carnassiez* or last of the series, and the first of these is conspicuously much smaller than the second; in *T. microua* the two are of equal or nearly equal size, and occupy more space longitudinally.

Both scissor-teeth are indeed most developed in *T. microua*, and the teeth generally are more robust.

The specimens of *T. microua* from Asám, like those of the Nepal, have generally a very minute tail, which can at least be distinctly enough felt under the fur; but those from the vicinity of Darjiling have no external trace of tail, whether sent as skins or in spirit. I have found, however, no perceptible difference in the skulls and dentition, nor in any other character whatever, that should warrant us in considering the tailless Darjiling Mole as a distinct species, separable from *T. microua*. The Society's museum contains *T. leucura* stuffed and in spirit, and the skull of the specimen preserved in spirit has been extracted and cleaned; while the dentition of the stuffed specimen is exposed, and is quite similar to that of the other here described. It is not improbable that *T. leucura* may extend its range eastward into China; and in that direction we may look for additional species of *Talpa* if not also in western Asia. In Africa the genus is unknown, but is represented in the south by *Chrysochlore*; in N. America by *Scalops* and *Condylura*; while in S. America the *Insectivora*, Cuv., do not occur, their functions being performed by numerous diminutive species of *Didelphys*, as also may be said in Australia by the *Perameles* tribe; and it is far from unlikely that Australia may yet be found to produce a fossorial marsupial form, resembling the Moles as other *Marsupialia* present an analogical but superficial

## TANKOEBAU PRAHOE.

likeness to certain other *Insectivora*.—*Journ. Ben. As. So. p. 215, No. III. of 1850.*

(2861) TA-LAIN-NO, *Burm.* is a vine which attains a diameter of eight or twelve inches. Fruit yellow, pear-shaped, acid, with six or eight stones, size of an egg.—*Malcom, Vol. I, p. 180.*

(2862) TALLE TANGA, the Malayala and Tamil name of a tree, which grows to about two feet in diameter, and thirty feet high. It is the tree that produces the jungle-almond, on which the monkeys and other animals of the forest feed. The natives cut this wood into boards for boats and house-building: they also make it into canoes, which are said to be durable. The boats are sewed together by coir-yarns.—*Edye, M. and C.*

Chotee Mue.

This plant sometimes secretes a saccharine matter allied to manna caused by a species of coccus which attacks the tree. A shower of this kind of manna fell at Agra in February 1855.

(2866) TAMBOGUM in Tamil, and Vanponga in Malayala.—This tree is remarkably heavy and close-grained, and was considered very similar to the timber then imported into British dock-yards from Africa, named African Teak, No. 1. It grows from thirty to fifty feet long, and about thirty inches in diameter, and is used by the natives where strength and durability are required, and weight is of no consideration. It produces a fruit or berry, which the natives reduce to meal, with which they make cakes, curry, &c.; the berry is much like coffee in shape and size.—*Edye M. and C.*

(2867) TANGUNS, Retanguns, or tanyans, of Nepaul, so much esteemed in India for their hardness, come entirely from Upper Thibet; and, notwithstanding their make, are so sure-footed that the people of Nepaul ride them without fear over very steep mountains and along the brink of the steepest precipice.—*Smith's Nepal.*

(2868) TANI in Tamil, Jellam in Malayala, which means waterwood. This tree grows to about two feet in diameter, and forty feet high. It is remarkably soft and porous, and contains a great quantity of water: when it is felled it is of little use; and is considered as one of the inferior kinds of jungle wood.—*Edye, M. and C.*

(2869) TANKOEBAU PRAHOE, a volcano in Java, with a crater from which the eruptions of 1829 and 27th May 1846 issued. Dr. Horsfield paid a visit to it in 1804.

## (2870) TANK KESRA OF CTESIPHON.

This building formed part of the Royal palace of Ctesiphon, and is called by the Arabs Tank Kesra. The palace was commenced by Sapor II, the ninth King of the Sassanian dynasty, at the beginning of the fifth century. It was added to about a century later by another king of the same line, Nooshirwan, usually called Khoosroo I, and was finished by his grandson, Khoosroo Perweez or Khoosroo II. The part remaining is merely a portion of the facade and one of the halls of audience,—not a tenth part probably of the original building. It was covered with brilliant white stucco, and the halls were decorated with historical paintings and figures of the heavenly bodies. It was taken from the Persians by the Arabs in the time of the Caliph Omar, in the sixteenth year of the Hejra, and was called by them the "White Palace." Its splendour and magnificence as related by the Arabian historians is scarcely credible. The dimensions of the hall are,—105 ft. in height, 95 ft. in width, and 180 feet in length.

The building remained entire till the time of the Caliph Al Mansoor, who endeavoured to destroy it in order to make use of the materials in the construction of his Palace at Baghdad. At the close of the ninth century, the Caliph Muk-tassi Billah regularly unbuilt the White Palace, in order to erect his famous edifice called the Taj, at Baghdad, and merely left this hall as a specimen of the Sassanian Architecture.

(2871) TANA, the Tamil name of a tree which is hard and heavy. It is used by the natives in house-work, and for implements of agriculture when it can be procured. It is very scarce.—*Edye. M. and C.*

(2872) TAN TAE HOEY of Singapore. A description given of the initiation into this Combination is as follows:—

About 7 o'clock they had all arrived and commenced to eat and drink spirits, which they did with a noise like battle. In about an hour this finished, when they commenced to play on drums &c. the music of which was exceedingly loud. On this they all arranged themselves in order sitting opposite the Datu, (idol) but I observed that their faces were as red as the Bunga Rayah, from drunkenness. Among them all there was one chief, who sat on a lofty chair, with two men standing at his right, and two at his left. After them came eight men with drawn swords, who arranged themselves, at the right and left; then came one man, who burned paper in front of the idol (sacrifice), after him came eight men, with drawn swords who guarded a man with dishevelled hair, and without any upper garment, in fact he had only a pair of trowsers. This man came in front of the chief, and bowed down till his head touched the ground, the armed men on the right and left now advanced, shouting, and laid their swords on his neck, they remained

silently in this position, for a short time, when a man advanced to the candidate's side. The chief then spoke as follows in the Chinese language, (this was translated afterwards at my request):—"Who are you, and from whence come you? Who are your father and mother? Are they still alive or are they dead?" These questions were explained to the candidate by the man who stood at his side, and were answered as follows:—"I am such a one, of such a country, and my father and mother are both dead," even if his father and mother were alive, he would be obliged to say they were dead, because no one whose father and mother are alive, can be admitted into the society, as the existence of all those is as if they were dead to the world and its ties. The chief then said, "will you swear that your father and mother are dead?" He answered, "I will," and performed the oath by burning paper in front of the idol, saying at the same time, "my father and mother are dead." The chief then said "what have you come here for?" answer "I wish to join the Tan Tae Hoey." These words mean the sky, the earth and man.

The chief then said "you are deceiving, your thoughts are not as your speech" answer "I will swear that I am in good faith"—"then swear," the candidate then taking paper, burned it while he repeated his assertion. The chief then said, "are you acquainted with the rules of the society?" answer "yes, I understand that I am required to take an oath, by drinking blood." The chief then said something to which the following answer was made:—"I promise not to divulge the secrets of this society to any one under penalty of death." The chief said, "truly"—answer "truly." A vessel was then brought containing arrack and a little blood from each of the members of the Society, and, with a knife, was placed in front of the idol. The candidate then taking up the knife made a slight cut in his finger, from which he allowed some blood to fall into the cup. The chief then said "drink in presence of Datu Peking." The candidate then drank a small cupfull, on which the chief, and all the confederates, drank a little, each in his turn. The chief then said "to-morrow go to our Secretary, and ask him for a book, in that book you will find all our rules and secret signs; you will pay one dollar for it." The chief then rose, and himself raised the candidate from his prostrate position and now being initiated, he can take his place among those who, before, would have considered him an enemy.—*Statement of Abdoolah bin Abool Kadir Moonshee.*

(2873) TÆNYO, *Burm.* PINE, of several varieties, is abundant in the dry and hilly districts, reaching a good size, often fifty feet without limb. One or two species are found in the Tenasserim provinces, but not frequently. It is neglected as timber because of its softness and exposure to

## TAXIDIA LEUCURUS.

ants. Some turpentine is manufactured from it. Pieces of it are every year washed down the Irrawaddy. As all India now depends on European and American spars, which often sell at most exorbitant prices, it is probable that Burmah will one day be enriched by the export of spars.—*Malcom*.

(2874) TAPOZOUS LONGIMANUS, a bat described by General Hardwicke. There are three Indian species of this genus.

(2875) TASMAH BAZEE THUGS. A Hindoostanee term applied to a class of these professional murderers of India, who destroyed their victims by means of a Tasmah or belt.

(2876) TATTOOING. The people of Burmah still follow the practice of tattooing their bodies, tracing on various parts, the figures of animals or plants, in a manner so pleasing that British officers have often been attracted to submit to the painful and barbarous process. The Hindoo women of Southern India, likewise occasionally tattoo their fore-arms from the wrist to the elbow.

(2877) TAU-MA-GYEE BURM. (*Elæocarpus*) is generally very large. Grain, clear and straight; timber highly prized.—*Malcom*. V. 1. p. 188.

(2878) TAN-THE-AH BURM. (*Hopea floribunda* of Wallich). Very large, somewhat abundant, and a useful timber. *Malcom* N. 1. p. 188.

(2879) TAWNI in Tamil, TANIKI MARUM in Malayala.—This tree grows to about three and a half feet in diameter, and from thirty to forty-five feet long; it is of a whitish colour, and is used by the natives for catamarans, canoes, &c. It produces a fruit which the native doctors use as a purgative, in cases of fever, &c. the timber is not durable or of much use.—*Edye, M. and C.*

(2880) TAXIDIA LEUCURUS, the Tibetan Badger.

Carnivora.

Subplantigrada,

Arcto galida. H. Smith.

Genus Meles.

Subgenus Taxidia.

Species new. T. Leucurus, Hodgson.

Tumpha of the Tibetans.

Habitat. The plains of Tibet.

There is not yet, I believe, any record of the Badger as an inhabitant of the east. The occurrence, however, in the sub-Himalayas of the allied forms of *Helictis*, *Urva*, and *Ursitaxus*, has led me for some time past to expect such a discovery in the Himalaya or Tibet, and my anticipations have just been fulfilled by the receipt of a very fine specimen of the Badger from the neighbourhood of Lassa.

The Tumpha or Tibetan Badger is in total length 37 inches, whereof the tail, with the hair, is 10 inches, and without it 7. The head is  $5\frac{1}{2}$  inches, the palm and nails  $3\frac{1}{8}$ , the planta or rest of the hind foot, from heel to end of the nails, 4, the longest claw or nail,  $1\frac{1}{4}$ , the ear  $1\frac{1}{4}$ , the

## TEMBOW.

longest hair of the body,  $4\frac{1}{4}$ . The aspect is entirely that of a long-tailed Badger, with somewhat smaller head and longer finer fur than usual. The small head is conico depressed with remote ears and eyes, and sharp elongated face. The muzzle or rude extremity of the nose is clearly defined, rounded, prolonged beyond the teeth, and has an abrupt oblique termination in front. The oval nostrils are opened entirely to the front, their lateral prolongation being merely linear and very much curved. The lips are thin and almost void of moustaches, and there is a still fainter indication of the tufts proper to the cheeks, chin, and eyebrows. The small pig-like eyes are situated midway between the ears and tip of the snout. The ears are oval, well developed and tending to a point.—*Mr. Hodgson in Jour. Ben. As. Soc.*

(2881) TAXUS BACCATA. Himalayan Yew.

Thoono, HIND.

Thuneer, „

Zurnub, HIND.

The leaves of this tree are sold in the Bazaars of the N. W. Provinces of India, under the name of "Burmee" or "Zurnub." *Taxus baccata* "Tingschi" is the yew whose timber is red. It is comparatively scarce in Sikkim.—*Hooker, Vol. 1, page 45.*

(2882) TAY, BURM. Ebony, vide *Diospyros ebenum*.

(2883) TEA. In 1858, Dr. Jameson up to the middle of March, had dispatched 5,300lbs. to the India House. He had sold about 12,400lbs. to the public at large, and made over 27,200lbs. to the Commissariat. So soon as Rohileund was re-occupied, he would have from 17,000 to 18,000lbs. ready for the Commissariat, or a grand total of 62,900lbs. Above five lacs of seedling plants and 36,000lbs. weight of seed had been sold in the course of the year to private parties.—*Bombay Standard, April 17, 1858.*

(2884) TEJBUL. Capsules and seeds of several species of *Xanthoxylon*.—*Ben. Phar.*

(2885) TELLE, or PAYANE, the Tamil and Malayala names of a tree which is found on the coast of Malabar and in Travancore, about sixty feet in height, and two feet and a half in diameter. It is an inferior sort of pine, and is named by natives Dupi-marum. It produces an inferior sort of damar, or resin, which is boiled down with cocoa-nut oil. When thus prepared, it is a substitute for pitch or resin, but very inferior. The wood is used for the masts of pattamahs, catamarans, canoes, &c., but it is not durable.—*Edye, M. and C.*

(2886) TEMBOW, or BLACK-HEART WOOD. It grows in the Malabar forests to about eighteen inches in diameter, and from twenty-five to thirty-five feet in height. It is considered a useful wood by carpenters for general purposes in house building, and for native

## TENASSERIM PROVINCES.

vessels, and implements of agriculture.— *Edye M. and C.*

(2887) TENASSERIM PROVINCES, being remarks on their Metalliferous Deposits and Mineral Productions, By EDWARD O'RILEY, Esq.

The principal metallic ores of these provinces of which the localities are known, are those of tin, antimony, iron and lead (galena); in addition to these however, specimens of the carbonate of lead, the sulphurets of copper and bismuth, and an ore of silver in combination with copper and antimony, have been obtained through the agency of the wandering tribes of Karens who inhabit the hilly regions of the provinces; the sites of the latter have still to be investigated; but such researches must be the work of untiring application to secure the good will of these sons of the forest, whose local experience is so intimately connected with the end to be attained.—

The known localities of the *stream tin* are as follows :—

1. The mines of Malewan and the tributaries of the Pakchan river.
2. On the Bokpyn river to the northward of the above.
3. In the upper branches of the Lenya river.
4. On the Thengdau river in the vicinity of the coal mine on the Great Tenasserim.
5. At Thaban-liek on the little Tenasserim river.
6. At Kamoungtan, Engdan and Thapyan in the same locality, but not so accessible as Thaban-liek.
7. At Yamon about 20 miles from Mergui, on the south side of the Great Tenasserim river, of an inferior quality, being mixed with wolfram sand or tungstate of iron.
8. In the Toung Byouk valley, a little to the southward of Tavoy river.
9. At the head waters of the Great Tenasserim to the eastward of Tavoy—noticed by both Dr. Helfer and the Rev. Mr. Mason.
10. In the upper courses of the streams which flow into the Bay of Henzai (a beautiful spot on the coast situated between Tavoy and Ye) the ore obtained from this locality contains grains of gold and garnets.

### Mine Tin.

11. Is found in the hill of Kahan near Mergui in a decomposed granite matrix passing through the sandstone. This hill is in fact a repository of mineral wealth which not even the richest (Tin) mines of Cornwall can excel, as will be seen from the remarks which follow.

The following statement shews the ascertained relative qualities, and the cost of production of the tin deposits of Banka, the Malay Peninsula, and these Provinces at a cost of per cwt.

100 parts Banka ore yield	58 parts of metal...	Rs. 11	6	As.
do. Malay Peninsula	do. 65-77...	" 13	4	"
do. Mergui Province	do. 70-75...	" 13	10	"
do. Kahanode Tin	do. 80-82...	" 13	10	"

## TENASSERIM PROVINCES.

Captain Tremenheere reports as follows, to Government on the tin deposits of the Mergui provinces (31st August 1841.)

"The streams themselves are rich in tin, which may be collected from the beds in considerable quantities. The process by which it has been deposited for long periods and for many miles along the line of valleys throughout which they flow, appears to be in active operation at the present day—crystals of the peroxide of tin washed down by the rains and deposited with sand and gravel in their beds may, by changes of the rivers caused during the freshes, be quickly covered with a few feet of gravel and soil. The older deposits have, as far as my observation extends at present, the same alluvial character, and it would be well in future operations to have regard to the levels in which the streams may have formerly run.

"First locality visited.—The Thengdau river, on the Great Tenasserim. A Shan employed for the purpose collected at this spot 11,889 grs. of ore, equal to 190.198 grs. pure metal, in an hour and a half.

Second locality visited.—Tha-ban-liek, on the Little Tenasserim. Great production in the bed of the stream. The produce of a day's labour of two men ascertained : 5 lbs., 2 oz., 383 grs. of pure tin, at a cost of 12 annas, exclusive of the expences of reduction to the metallic state.

From the trial of the produce of one man's labor in a given time, there appears to be sufficient to justify every expectation of a profitable employment of labor on an extensive scale : the result can only "be considered rough approximations to the probably outturn of tin with an establishment properly superintended."

Kahan, a small hill on the right bank of the Great Tenasserim, 4 miles from Mergui. "The tin occurs here differing much from that of the localities above mentioned; the hill is composed of a soft friable white sandstone rock, the ore is found in the crystallized form interspersed in decomposed granite, forming a vein about 3 feet wide enclosed by the sandstone rock.

"In about a quarter of an hour a few baskets of the decomposed granite were removed, which produced an amount of crystallized peroxide of tin equal to 63,176 grs. of pure tin.

"This locality appears to be of a very promising description, and I have little doubt that if the work were aided with ordinary skill and means, a tin mine here would be exceedingly productive. A vein of tin is in fact exposed to the day, and, and would only require for a considerable period of work, the precaution of well supported galleries and shafts to allow of its contents being easily extracted.

"The Kahan hill is I conceive an indication of a valuable repository of tin. It is but a quarter of a mile from the creek communicating with the river, which is accessible to any boats. Its

## TENASSERIM PROVINCES.

proximity to Mergui offers also great facility for procuring labor and supplies.

"The localities therefore which appear to hold out the best prospect for tin ore, are for stream tin the Tha-ban liek and Theng-lau, and for mine tin Kahan hill. They all produce tin of the same nature and quality, viz. crystals of native peroxide, being a combination of oxygen and tin only.

"The crystallized form in which the ore has been found renders its separation extremely easy, and the whole process of stamping and dressing, which in England are tedious and expensive operations can thus be dispensed with, no arsenic or sulphur being mixed with the ore, it need not be roasted before it is placed in the furnace.

It will thus be seen that the tin of Mergui offers no ordinary inducement to the outlay of capital, without much of the risk, uncertainty and large previous outlay usually attending mining adventures."

Captain Tremenhare's second report to the Military Board on the tin of Mergui, October 1842, after noticing the rich deposits of "Kahan" proceeds as follows:

"Experimental operations have been in progress there by the order of the Commissioner Mr. Blundell, with a view to ascertain the value of the spot for mining purposes, and I am happy to have it in my power to state, that they have been attended with the most complete success; more than 8 cwt of the ore ready for smelting has been collected by a gang of convicts, in which are bulky specimens of maced crystals, which in weight and size surpass any thing I have ever seen in Cornwall or in cabinet specimens.

"The upper portions of the decomposed matrix of the ore which have been exposed to view at the surface, appear but indications of a most valuable repository of tin, from which have been extracted specimens of great weight and richness, consisting of large maced crystals of tin on quartz, and contain more tin in proportion to the bulk than any specimens I have before seen—the largest, which measured about 14 inches square by 12 deep, was so heavy, as to require some exertion to hold it steadily in both hands. The stratum of tin soil was ascertained to be upwards of 12 feet thick! The "Kahan" ore gave on analysis only 0.91 per cent of metallic iron and is believed to be pure from the tungstate of iron and sulphur."

Captain Tremenhare reports as under, on the tin deposits of the Pak-chan.

"Malewan and the tributaries of the Pak-chan. The greatest quantity of clean ore obtained from one trough full of soil was 2,078 grains; the time occupied in each washing 5 to 6 minutes.

The workmen stated that in the rains one man would even earn four rupees worth of tin per day. These productive seams are however

## TENASSERIM PROVINCES.

but the index of what is to be found elsewhere, and if these localities ever attract the European capitalists, of whose notice I have believe them well worthy, the proper sphere for the scientific miner should be in the hills themselves. There, if a little cautious investigation were previously made by practical men in search of a spot for mining operations, the use of the common horse "whem," or the most ordinary draining operations, would in my opinion, in the course of a very short time, discover veins which it would be very profitable to follow out with more complete apparatus." The late Dr. Helfer in his letter to Mr Commissioner Blundell on the tin deposits at the head of the Great Tenasserim writes thus: "I have made one excursion to the eastward from this place (L'avy) crossing over the Tenasserim river to the supposed boundary: my chief aim was the tin mines, and I am greatly satisfied with them; they are very productive and very extensive; only, because the people do not understand to work them, and because no European who understands it knows of them, they lie waste; but on a large scale worked with a capital of 20,000 rupees to commence with, one would soon become a "millionaire."

Of the value of such testimony as the foregoing there can be but one opinion; coming as it does from an officer of known scientific attainments and well acquainted with the vast mining operations of his native country. The wonder is, that the Supreme Government of India should have allowed these reports to pass into oblivion for so long a period, instead of causing them to be circulated through the capitalists at home, with offers of the most liberal consideration to any parties undertaking their development.

*Antimony.* The sulphuret ore of this mineral appears to be pretty general throughout the provinces; accompanying the sandstone of the older formation, in which it is found forming veins of various dimensions which ramify in all directions from the principal vein. Several localities in the sandstone range of hills enclosed by the Attaran and Maulmein rivers have been worked, but it would appear that the expenses attending the operation are too heavy to admit of a profitable investment of capital therein, the localities of these deposits being generally at some considerable distance inland, without roads and water or water conveyance in the vicinity, and the labour attending its extraction from a hard matrix of the nature of the sandstone, oppose a formidable barrier to this article ever becoming important in the exports of the provinces; and until it be found in the mass on the banks of some of the navigable rivers, or similarly situated to the deposits of Borneo, the competition with the Singapore market to supply the limited demand in the home markets must remain as now, impracticable.

*Sulphuret of Bismuth* occurs with the ore

## TENASSERIM PROVINCES.

of antimony in the sandstone range of hills described in noticing that ore; its importance as an article of commerce is of secondary character, but should it be found to be present in any considerable quantities, the reduction of the metal from the ore would doubtless prove profitable, its price for the home demand being from 2s. to 2s. 6d. per lb.

**Gold.** Has been collected in small quantities from several of the tin streams having their sources in the older formation of the boundary range of mountains; that obtained from the head waters of the Tavoy river, as also from the streams which empty themselves into the Bay of Hénzai, where it is found mixed with the tin ore, is of a quality equal in every respect to the gold dust of the Malay peninsula. It does not however appear to be in sufficient quantities to induce the establishment of permanent washings, altho' the Siamese have for many years derived a considerable revenue from the produce of the streams which form the eastern watershed of the same range of hills.

**Coal.** The tract of country enclosed within the 11th to the 14th degree of north latitude, may be said to form a vast coal bed, or series of coal measures, and in that space, principally in localities through which the great Tenasserim river and its branches flow, coal has been discovered in six different outcrops, widely separated from each other and as widely varying in the quality of their deposits. Of the whole of the foregoing, but one single locality, situated on the great Tenasserim river in lat. 12°21' N, and long. about 99° E. and distant from the port of Mergui by water about sixty miles, has hitherto claimed the attention of Government in the extraction of the coal. The quality of the material thus obtained will be evident from the following analysis of it made by order of the Bengal Coal Committee in 1840.

*Spec. grav. 1.27*

100

Notwithstanding this favourable exposition of its quality and adaptation to steam purposes, and the cheap rate at which it could be laid down for the steamers at Mergui, viz. 5½ annas per maund, the undertaking was abandoned shortly after its commencement, on the discovery that the coal passed the dangerous property of spontaneous combustion, to which cause the loss of the Steamer "Madagascar" on the coast of China, which had taken her supply of fuel from the coal of the Mergui mine, was attributed.

By far the most important discovery of coal in these provinces is that which was examined

## THIBET.

and reported upon by the late Dr. Helfer, situated at the source of the little Tenasserim river, where it is found out-cropping at the surface in five different localities, forming the same bed, the quality of this deposit appears from the following analysis of it to be unexceptionable, not excelled in fact by the best English coal for steam purposes.

The quantity exposed to the day would indicate an inexhaustible supply below, and as the process of extraction in the first instance to the extent of many thousands of tons could be confined to open workings, without the necessity of expensive appliances of machinery, the question naturally arises, why has this invaluable deposit been neglected, and what are the present existing causes that retard a further investigation of it.—*Journ. of the Indian Archipelago, December 1849, p. 379.*

(2888) **THIALICTRUM FOLIOLOSUM**  
NAT. ORD. Anemoneæ. Pelijurree Hind : grows at Mussorie and the Himalayas generally. Its root in doses of 5 to 10 grains, acts as a tonic and aperient and is given in the interval of intermittent fevers and in convalescence from acute diseases. It promises to succeed well as a febrifuge of some power and an aperient of peculiar value.—*O'Sh. p. 161.*

(2889) **THANY MARAM.** This is a tree common about Nelambore and in Coorg; wood much used but not durable being very liable to be attacked by insects.—*McIvor, M.E.*

(2890) **THIBET**, is reckoned by Gutzlaff in his 'Life of the Emperor Taou Kwang,' page 227, to comprise an area of 30,200 square miles; and to have a population of about six millions. Thibet, as thus indicated in the enumeration of the dependencies of China, embraces, I believe, Little Thibet or Balti, the capital of which is Iskardo; Western Thibet the principal town in which is Leh and Thibet Proper or Eastern Thibet, having Lassa as its capital and chief city.

The latest and best account of the Trans-Himalayan regions, is 'Dr. Thomson's Travels,' published last year in London.

Following Humboldt, Dr. Thomson divides Thibet into two grand divisions: the western one, of which he treats so ably himself, and the eastern one, to which alone my notes refer. Western Thibet—according to Dr. Thomson "is a highly mountainous country, lying on both sides of the Indus, with its longer axis directed like that river, from south-east to north-west. It is bounded on the north-east by the great chain of mountains, to which Humboldt, following Chinese geographers, has given the name of Kounlun, by which it is sepa-

rated from the basin of Yarkund. On the south-east, its boundary is formed by the ridge which separates the waters of the Indus from those of the Sanpu." "To the north-west and south-east," continues Dr. Thomson, "its boundaries are somewhat arbitrary, unless the political division of the country be had recourse to, which, depending on accidental circumstances, entirely unconnected with physical geography or natural productions, is so liable to change that its adoption would be extremely inconvenient. The best mode of drawing a line of separation between India and Thibet, in those parts where mountain chains are not available for the purpose, appears to consist in regarding the latter to commence only at the point where the aridity of the climate is too great to support forest trees, or any coniferous tree, except juniper."

"As limited by these boundaries, Western Thibet includes the whole valley of the Indus, and its tributaries down to about 6000 feet above the level of the sea: a considerable portion of the upper course of the Sutlej down to between 9,000 and 10,000 feet, and small portions of the upper course of the Chenab, of the Ganges (Jahnāvi) and of the Gogra."

The above is a very elaborate definition of boundaries, founded mainly, as regards the limits of India and Thibet on the geographical distribution of plants. By it the Himalaya, so well known to Dr. Thomson, is annihilated as a mountain chain. The Kounlun however which no body knows anything of, and which may be quite as frequently cut through by meridional rivers as the Himalaya, is admitted to that distinction.

I shall now endeavour to describe the second grand division or "Eastern Thibet." It is by all accounts an exceedingly mountainous country, i. e. it contains immense masses and ranges of the most rugged mountains in the world interspersed with extensive plateaus and deep level-bottomed valleys along the streams and rivers.

The Thibetans I have met with, do not recognize a continuous chain of mountains running parallel to the Himalaya; nor are they acquainted with "Kounlun" as the name of any mountain range. They are familiar with the Himalaya on one hand and call it "Kangri," which simply means, *Snowy region*, and they know that the country of the Mongols, or Mongolia lies parallel to it on the other hand. The third great distinguishing feature in the physical geography of Eastern Thibet is the Yaroo river or Sanpoo of our maps. Thus characterised, I shall say that in popular estimation—which is not founded on the physical features of the country, on its natural productions, or on political divisions of territory, separately or jointly,—Eastern Thibet is bounded on the north-west by the Kangtisee range of mountains, [Note. The highest portion of the "Kangtisee" range is I

believe the "Kylas," of Strachey] and a greatly elevated tract of country extending from the base of this range; on the north by Mongolia; on the east by the Sifan and Sechuen provinces of China, and on the South by the Himalaya, from the point at which it is pierced by the Burampootur on the east, to the meridian of the Mansarowur and Rawan Rud Lakes on the west. The general direction of the Kangtisee range is north and south, and it is said to connect the Himalaya and Mongolia, as by a cross-bar. It runs to the east of the Mansarowur Rawan Rud Lakes, its highest point is said to exceed in elevation any portion of the Himalaya, and four large rivers have their sources in different parts of the range, viz, the Singh Khawab or Indus, the Langehoo Khawab which runs through Ladak, the Marchace Khawab which is known as the Gogra, and the Tamchoo Khawab or Yaroo, the great river of Eastern Thibet.

*Government of Thibet.* In the city of Lassa, and over the whole of Thibet "Geawa Remboochi" or the "Grand Lama" is nominally the supreme authority, in temporal and spiritual affairs. His residence is in Patala Goompa which is on the north side of Lassa. M. Huc says, that "Lassa" in the Thibetan language means, "Land of spirits." The Mongolians on the same authority call this city "Monche-dhot," i. e. Eternal sanctuary. My friend Cheboo Lama gives the following interpretation, "L'ha" means God, "Sa" abode or resting place. Hence it is the city of God, or the Eternal city.

There are two Resident Envoys from China called "Ampas" stationed at Lassa; subordinate to them are two great officers—Chinese, designated Daloo-he: their rank and occupation are those of general officers. Next to these are two Phopuns who act as Paymasters of the Troops, and perform the duties of our Adjutant and Quarter Master Generals. They are also Chinese. One of the Daloo-hes, and one of the Phopuns are generally stationed at Digarchi. These officers constitute the general staff of the army in Thibet. Next in rank are three Chonghars. They are Chinese, and Military Commanders; one is generally stationed at Digarchi and another at Tingri near the Nepal Frontier of Thibet. Below these are three Tingpuns, non-commissioned officers—also Chinese. There are no other Chinese military officers in Thibet. The usual number of Chinese Troops, all Mantchoo Tartars, in Thibet, does not exceed 4,000 men. Stationed at Lassa 2,000, Digarchi 1,000, Giangtechi 500, Tingri 500.

The above shews that the Chinese functionaries in Thibet are Political and Military Officers only.

All the Civil appointments are held by Thibetans. The local temporal Government of Thibet is headed by the Grand Lama entirely guided in all Political and Military affairs and mainly so

## THIBET.

in Civil affairs by the Chinese Ampas and the Emperor of China.

The first officer is the Chemeling, the second Kandooling, the third Tengeling; they are all Thibetans and the Chief Lamas—Awataris—of Goompas bearing those names. The Principal Goompas at Lassa and its vicinity, are the Genden Goompa..... 3,500 Lamas resident and itinerary.

From the three Lama Counsellors, the emperor of China nominates the Noume-hen, "Nome Khan" of M. Huc, who may be called President of the Council, or Prime minister. Gealchup Noume-hen is the proper title which being translated is "the image of Geawa" or the Grand Lama. He is Regent when the Grand Lama is a minor, and at all other times is the alter et idem of his holiness. The Noume-hen is always one of the three Great Lamas above named. At his death, or removal from office, he is succeeded in the Noume-hen's office by one of the two remaining counsellors, always however under orders of the emperor. His successor must, as in the case of a "Grand Lama" be an awatar, i. e. he must re-appear in the flesh as a child, and be raised to that position.

Of equal rank with the Noume-hen but having no temporal authority, is the Genden Tapa Lama, he is next to the Grand Lama himself the highest clerical authority. He is finally appointed by the emperor, being in the first instance chosen on account of his superior attainments and sanctity by the local authorities. He is chief of the great monastery of Genden. The persons privileged to take a part in the selection and recommendation of the Genden Tapa, for his holy office, are the Noume-hen, the two Ampas and the four Shapees. They propose him for election to the Grand Lama, after his approval, the Ampas procure his appointment from the emperor. The Genden Tapa, is chief Lama of a Goompa, but not an awatari Lama.

Next in rank and power to the Noume-hen are the four Shapees. They are not Lamas, always Thibetans and the principal executive officers of the Government in the Financial, Revenue and Judicial Departments. These departments are not separated and under distinct officers. The Shapees are the highest Judicial officers in the Civil and Criminal Courts. Next to the Genden

## THIBET.

Tapa is the "Lama Yeungjing" the private guru, or high priest of the "Grand Lama." He is also appointed by orders of the emperor, and is sometimes an awatari Lama, but not always. His office is to teach and train the Grand Lama in childhood and youth, and lead him, if he can, afterwards. This is indeed an important personage in the Bhuddhist world, being no less than the keeper of the Grand Lama's conscience. The nomination to this post being in the hands of the emperor, furnishes an interesting clue to the extent of the imperial power over the church of Thibet.

The Che Kap Kempu Lama is a churchman of great influence in the Government. He appears to represent the Grand Lama in the council of state and in the deliberations of the Shapees. He may be called Secretary or Minister for the church, and the Shapees may, correctly enough, be called the Financial, Judicial, Revenue and Home Secretaries, or ministers.

The Treasury is managed by two officers named Jhassas; both are Lamas, and act conjointly, although one of them is Treasurer on behalf of the "Grand Lama," and the other on behalf of the Noume-hen or temporal estate. They are assisted by two Sub Treasurers styled Shangjotes. Four officers designated Da-puns are the commanders of the Thibetan Troops, and act as Civil and Political Commissioners on occasions of frontier or other disturbances, they are Thibetans, and not Lamas. The ordinary course of official promotion is from a Da-pun to a Shapee; of equal rank, to the Da-puns is the Che-pun who is however a Civil officer and acts in all Departments as Deputy to the Shapee. Shate Shapee was the energetic Commander-in-Chief of the Thibetan army which opposed the Nepalese under Jung Bahadoor. The Shapee, is often employed as Commissioner on Deputations in Civil affairs either Judicial or Fiscal, and all the cases sent up by the Police for trial before the Shapees are forwarded through this officer. All appointments to the offices above noted, require the confirmation of the emperor.

1. *Tinkpun*—Superintendent of Police and Jails.

2. *Sherpankpa*—Assessors to the superintendent and to act as checks on his proceedings.

3. *Boopun*—Military officers subordinate to the Da-puns but also employed in Civil affairs when required.

4. *Jongpuns*—Collectors of Revenue and Magistrates in the interior. They hold office generally for three years only. They are all laymen, one of these officers who is employed in the district of Gar known, to us as Gartope, is named the Garpun. He has charge of the salt and gold-diggings in that direction both of which are valuable. In the Kampa country to the East of Lassa, these officers are styled Markam tois.

## THIBET.

5. *Giapuns*.—Subordinate Military Officers, non-commissioned.

6. *Dingpuns*.—Ditto, ditto.

7. *Choopun*.—Ditto, ditto, privates are called Ma Mi, which means "fighting men."

The patronage of these seven classes of officers nominally lies with the Gealchup Noume-hen, but the Chinese Ampas have a veto if they desire to exercise it, and the working of the system is to procure the approval of these high officers to the appointments before they are made.

One of the Ampas annually visits the Nepa and Ladakh frontiers. [Note. In 1846, Keshen was the only Ampa or representative of the Emperor in Thibet, but he was one of the eight Tongtongs of the Empire and specially deputed to arrange Thibet affairs at that time and the usual system of two Ampas was then suspended. The following anecdote of Keshen is very characteristic of the self-deceiving system of the Emperor's Government. When Keshen was ordered to be executed for having sold the interests of his country to the English during the War, his life was spared at the entreaty of "Sac Lama" the friend of the Emperor "Taokwong" and sentence of banishment in chains was substituted. Subsequently at the urgency of the same Lama, Keshen was appointed viceroy to Thibet. Affairs at Lassa, and throughout Thibet were in great confusion at the time; three Grand Lamas had died by poison in a few years and the Noume-hen was suspected of the crime. Keshen had the opportunity given him of redeeming his fame; and he did so by re-establishing order in the country, and convicting the Noume-hen. It is a curious fact, however, that he proceeded from his banishment in Manchouria to his Government at Lassa *in chains*, that is to say, he wore a gold chain, the badge of punishment round his neck, concealed by his garments, nor was it removed, and his forgiveness complete until after he quitted Lassa as Governor of Sechmen.] The Noume-hen and the four Shapees have the entire control of the land assessment, commerce, customs and other sources of revenue, and, I believe, that no account of the revenues, or the disbursements of Thibet are required by the Emperor. The Chinese Troops and all the Chinese officers in Thibet are paid by China and in money; the Thibetan Troops by assignments of the Government share of the land tax. There is no money Revenue sent to Pekin, an annual embassy with presents only in cloths, images, books, incense, &c.

There is a fund in Patala Goompa to which 100,000 rupees is added annually. Never opened except in time of great war expenses, it was opened to repel Zorawar Singh the Sikh General, who invaded Thibet from Cashmere in 1842. The Ampas pay is 140 Rupees per day, and

## THIBET.

from China, and he has lands and other emoluments from the Grand Lama.

*Army*. They have no Artillery in Thibet; the Cavalry so called is mounted on ponies; the principal troops are Infantry and great pains are taken to make them good marksmen. Prizes and promotions are the invaluable rewards of good marksmen. The Chinese or Tartar troops are kept quite distinct from the Thibetan ones, which are only a Militia called out when required, and not regularly paid. The Imperial Troops quartered in Thibet do not exceed 4,000 men, and the Thibetan force is not so strong. There are 2,000 Imperials at Lassa, 1,000 at Digarchi, 500 at Giangtchi, and detachments at Phari, and Tingri. The last named post, is on the high road from Cathmandu to Lassa, and is situated on a plateau called the "Tingri Maydan" by the Nepalese. The Imperial troops are armed with long matchlocks, to which a rest is attached. The Thibetans have very few firearms, being provided with bows and arrows, and short swords. The powder is of a very inferior description, and it does not appear that the troops are ever practised in military manœuvres.

### *Personal Habits, Customs and Ceremonies of Thibetans.*

The Thibetans of the higher class wear Chinese satins in the warmer seasons, and the same lined with fur in the cold; all others, male and female, wear woollens in the warm, furs and sheep skins in the cold weather, and never go about without boots. The men do not go about armed. The common people never wash during the cold season; very sparingly at other times. The reason given for this being that the skin of the face cracks and ulcerates from the cold, if water is applied to it. The people of towns, who do not go much outside the house, wash occasionally, but the universal prejudice is strong against ablutions of the person, and it is equally extended to their clothing which is worn in a filthy and greasy state.

Soap is high priced and little used in Thibet; it is not manufactured there. The supply is from India, through the Cashmere traders via Ladakh, and from Nepal. A small quantity also goes from Bengal through Bootan and Sikim. There is a grass in the country or a plant like grass, the root of which pounded with water, makes a lather and is used for washing clothes.

Travelling in the winter and indeed generally is performed on yaks. The women ride astride on them like the men, and they are so masculine and dressed so much alike that it is difficult to distinguish between them.

A Thibetan village or town is never surrounded with filth, as in India. To every house there is a privy, and the contents are carefully preserved for manure. In some situations, where the soil is suitable, saltpetre is made from the

## THIBET.

of this article, which is used for making gunpowder only, goes from India. [Note. At the time of the Sikh General, Zorawur Singh's disastrous incursion from Ladakh into Thibet as far as Gartope, 1842, there was a good deal of saltpetre taken into Thibet through Sikim, also sulphur and lead bullets.] In towns, the contents of the privies are sold annually, and those of people of wealth sell highest.

It is well known that the dead are not burned or buried in Thibet, but exposed on high places to be devoured by vultures. For this business there is a class of men who make it their sole vocation. They are called "Raga Tongden;" they are a low race held in dislike and shunned, but they are generally rich; they go about to the living, begging and extorting money. When refused or ill-treated, they retaliate with abuse which is often successful. "Very good," say they, "you won't give us alms now, you will come into our hands some day, and we will put a rope round your neck, drag your body through the streets, and throw it to the dogs," and the latter part is the frequent fate of the poor man's body, as these men keep numerous dogs to devour the bodies.

The bodies of the wealthy are carefully disposed of; they are carried in a litter to the top of a hill, set apart for the purpose, the flesh cut in pieces, the skull and bones pounded in a mortar, and when all is ready a smoke is raised to attract the vultures, who collect in thousands to eat it up.

The Chinese have spacious burial grounds at Lassa, and Digarchi, and there, as in their own country and wherever they reside, they are well cared for and ornamented. The Lassa one is said to contain 1,00,000 tombs. In the time of Wangh, a celebrated Raja of Lassa, there was an insurrection against the Chinese which ended for the time in the annihilation of the whole army, and the massacre, by the Thibetans, of the whole Chinese population. The funerals of the Chinese at that time were estimated at 4,000. This massacre was punished by the Emperor with signal vengeance, and since that time the Chinese supremacy has been finally established all over Thibet. There was a petty insurrection in 1843, in which many Chinese were killed.

*Religious Festivals.* There are twelve great annual Festivals, viz. Bunteung, Kansupecha, Chushupecha, Gesupecha, Nesupecha, Gosungpecha, Gyajeepecha, Lallupecha, Chindupecha, Dudupecha, Kagyurpecha, Lukphopecha, Pecha is equivalent to Puja.

On the anniversary of the death of a Chief Lama of a Goompa, there is a great festival and illumination. At Tashi Lumbu, three such are held annually.

The "Lassea Moran" festival of M. Huc is

## THIBET.

the anniversary of the first proclamation of the religion of Boodha by Sakya, at Lassa.

*Seasons.* The year is divided into four seasons. First Chid, or early Spring, February, March and April. Second Teuh, or Spring proper, May, June and July. Third Yirrh, or Rains, August, September and October. Fourth Gunh, or Winter, November, December and January. Some showers and southerly winds occur in Chid. In Teuh, it is temperate and dry, but showers, thunder and lightning occasionally prevail. In 1845, a great earthquake was experienced in the Province of Kham north-east of Lassa. It was most severe in the district of the Dirgi Raja. About 3,000 men were killed, and a Goomba destroyed by the opening of the earth.

About 20 years ago, the district of Kompo in the Province of Kham was visited by a severe shock; one village was destroyed by the opening of the ground. During Yirrh, there is constant but not heavy rain and hail in September and October. Frost begins early in November and increases all through the winter. Heavy falls of snow are rare except on the mountains.

*Soils.* Only three kinds of soil are recognized; a blackish one, a reddish one which is described as rather clayey, and a greyish coloured one, which is also clayey and contains a good deal of sand. The last is found along the beds of streams and yields good crops. The reddish soil is also fertile; it frequently contains gravel and stones; it is the prevailing soil in the tract called Dingcham, which extends along the northern face of the great Himalayan chain from Tamang to Keroong, but this region is quite barren. Mean elevation 16,000 feet at least. The blackish soil most abounds in the districts or provinces of Wand Chang; it is the most fertile of all, but also contains stones and gravel.

The fertility of the culturable soil is highly spoken of, and 40 to 50 fold in wheat is considered the average. Crops are generally very certain, and blights or other accidents rare. Early frost sometimes overtakes the harvest and spoils the grain, when the grass is at the same time burnt up, and this causes scarcity and famine. It is then the granaries are opened, and the corn-merchants make their fortunes. There is no interference with the price of grain. It is always dear compared with India, but varies considerably; and the principal cause of scarcity appears to be the early setting in of frost. This is said to be induced by continued clear nights which are greatly dreaded in harvest time.

*Agriculture.* Wheat, barley and other crops sowed in April and May are reaped in September and October; all are irrigated. The peach ripens at Lassa in October and November. It is sun-dried and preserved. No grapes are grown at Lassa. The whole supply of raisins is re-

## THIBET.

old cultivations : yaks, bullocks and ponies occasionally are trained to it. The plough is the same as the Indian one, made entirely of wood, except the stock which is pointed with iron. Timber for ploughs is imported from Sikim and Nepal. Rhododendron Hodgsoni, and birch-wood make the best ploughs. Cultivation in fresh lands is done with the hoe. The Thibetans do not use a harrow, the grain being covered in with the hand.

Barley in Thibet takes the place of potatoes in Ireland; four-fifths of the population live on it.

Neither wheat, barley nor peas will come to maturity as a paying crop in any part of Thibet without irrigation, and the water flooding of the fields, by which they derive a fertilizing effect from the frost, is equally necessary to prepare the soil for these crops. Wheat requires three or four irrigations or waterings from the time the seed is sown till the ear bursts, after which it will ripen without further watering. The flooding of the lands in winter, and watering of the crops in summer are principally effected from drains or canals cut from the rivers : very little watering is performed from wells. The whole of the arable lands along the Painom river and the most of it on the Yaroo Sanpoo are terraced and have maintaining walls of stone raised a little above the surface of the fields. Great pains are taken for the equable distribution of the water by running it off from terrace to terrace, and it is applied from leather bags when it cannot be brought to run on particular spots. Watering freely is indispensable to all crops in Thibet. The atmosphere is so dry and the soil so destitute of moisture, that without it the sun burns up the crop before it comes to ear. In a land of so little rain and with an atmosphere so dry and sun so scorching as to render irrigation and free watering indispensable, the questions which naturally arise are, what extent of area can be watered from the rivers by canals and drains? and is there more arable land in Thibet, than admits of being irrigated from the rivers?

To answer the first question, it would be best to refer to the statistics of the Nile irrigation, in illustration of the extent to which land on either side of a river may be irrigated by artificial means, not by the overflowing of its banks which is not usual by the Yaroo of Thibet, and is therefore not to be taken into the comparison. I have not the means of making this comparison. But to reply to the second question I have taken much pains to collect facts, the most prominent of which are as follow :—

1st. The culturable land on either bank of the Painom river, from its source to Digarchi, has not a maximum breadth anywhere of more than four miles, i.e. eight miles in all for the extreme breadth. In many places however, the river is

## THIBET.

Yaroo one day's sail, the culturable land on either side the Yaroo varies from two to four miles.

3rd. From Giangtchi till the Yaroo escapes from the Kambola range, its course is exceedingly tortuous, generally through great mountains, and it has but a very narrow bed of culturable land in a few places. It is closely pressed in by great mountain ranges in the Kambola district, and elsewhere in this portion.

4th. I allow the utmost extent of culturable land ever given to me by an informant for the Yaroo valley from the point at which it leaves the Kambola range entirely to the junction of the Kechoo or Lassa river; and that is a total breadth both banks included varying from 20 to 40 miles. There is more flat land on the South than on North bank of the Yaroo.

5th. The Kechoo river is closely hemmed in by mountains on the Eastern bank; on the Western bank it has a belt of about four miles of culturable land only.

These particulars will afford some assistance for reckoning the culturable area of the finest part of Eastern Thibet, and will shew it to be very small indeed, compared with the total area of this rugged country, and it is universally asserted that the land is every where dependent on river irrigation for its fertility. On this subject M. Huc says "Paulon, fine purple cloth, scented sticks and wooden bowls are the only good manufactures, neither is their agricultural produce remarkable. Thibet, being almost all covered with mountains and intersected by impetuous torrents furnishes its inhabitants with but little soil suited for cultivation, the valleys alone can be sowed with any prospect of reaping a harvest." When the Yaroo does overflow its banks, the sediment it leaves, is fertilizing. The Yaroo soil deposit is generally light and sandy.

Three feet of digging brings you to the water at Digarchi which stands in the flat and low Delta of the Painom and Yaroo rivers, 20 feet is required at Kambajong. Kambajong is a Police Station in Dingcham. See Hooker's Himalayan Journal and Map.

Many Thibetans believe that the Painom rises in Sikim, but its sources are no doubt, as given by Turner, in the vicinity of the Ramchoo Lakes, north of Phari. A horse Dak is four days from Digarchi to Lassa, a boat by the Yaroo takes 12 days to the disembarking place, nearest to Lassa. It is 12 days' journey to the salt Lakes from Digarchi, due north.

*Crops, Rotation of, &c.* The number of crops is very limited; wheat, barley, buckwheat, peas, turnips and a little mustard, comprise the whole. There is no regular rotation observed. As in India with all crops, so it is in Thibet. Wheat is grown for generations in the same ground var-

## THIBET.

about three times as much barley being grown as wheat. All the Suttoo eaten with tea is roasted barley, and this may be considered as the staple article of food for all travellers. See M. Huc, *passim*.

At Digarchi, Giangtchi and generally in the Province of Chang or Tsang, grain is more plentiful than in the neighbouring province of U; in the former 10 to 15 seers, (20 to 30 lbs.) of wheaten flour per Company's Rupee is reckoned cheap, and in the latter about half the quantity is so.

The dung of animals is so much in request for fuel, that scarcely any is used for manure, nor is there any spare fodder or other vegetable matter available for composts. Human ordure and ashes are therefore the principal manures in use; both are carefully preserved, and very valuable. In the towns the contents of public privies are a source of revenue to the Government, and lodging-houses have privies attached to them which are most jealously watched. The contents of these places are removed by a class of people who principally live by the occupation, and are the filthiest of all the population, which is everywhere and in every grade, very dirty. They work with their hands at their vile occupation and in the middle of it unwashed may be seen drinking hot tea, and eating raw and sundried flesh close to the piles of ordure. Ashes are mixed with the ordure, and this is reckoned the best of all manures. Liquid manure, (ordure with water,) is also in use, but sparingly. This mode of using manure is probably taken from the Chinese.

Scarcely any weeding is required, as the crops grow nearly free of all weeds. When necessary, it is done with the hand, the weeds being carefully preserved for the cattle.

The Thibetans reap with an untoothed sickle, the crops being all cut close to the ground to save the fodder. Wheat is tied up in small sheaves and stocked on the ground, or in yards near the houses. The corn is beaten out by the flail as in Europe, the women taking a part in the threshing with the men. This is done with great care, so that not a grain is lost. There is also a kind of hackle used for beating out the corn. A beam eight or ten feet long toothed with iron spikes, through which the sheaves are drawn. The winnowing is performed in the open air.

The grain is ground into meal by watermills. In some villages, mills are built by subscription, and the parties use them in turn. There are public mills also. The millers in these take one part in 20 as payment. There is a great press at the mills for two months after the harvest, when they are going day and night, as frost sets in November so hard that they cannot be used again till the spring. There are no windmills in Thibet I believe, although in no country in the

## THIBET.

World, I believe, is there a more steady wind in the cold season, than here.

*Wages of Labour.* A Chinese soldier is very highly paid in Thibet, i.e. he gets as much as 12 to 16 Company's Rupees per mensem. The Thibetan soldier has no regular money pay. He is allowed the Government share of revenue on a portion of land, his own farm or another, and this does not exceed 40 or 50 Company's Rupees per annum.

Masons, carpenters and other artificers can earn from eight as. to one Rupee a day in the towns; common labourers three and two annas. Gold and silver smiths are highly paid, eight as. in the rupee for fine work is the usual rate.

*Breads, &c.* The bread is all unleavened, and cooked on heated stones or gridirons. The poorer people make their bread with coarse wheaten flour and water, the better classes with fine flour and butter. The latter description I have eaten. It is a sort of heavy biscuit, made in a long twisted loaf-like shape. The sweet and pure farinaceous taste of the fine flour of Thibet equals the best Cape or American flour. Rice is only eaten in Thibet by the Chinese, and the richer Bhotias. The whole supply is received from Bootan and Sikim. The Thibetans do not cook and eat it plain as the Indians and Chinese do, but make it up into large balls with butter and sugar using it as a pudding and sweetmeat. The staple food of the country is "Champa," called Suttoo in India; it is finely ground flour of toasted barley. It is universally eaten and without additional cooking, and is excellently suited to the people of a country which is so ill-supplied with fuel. Mixed up with hot tea and formed into solid balls, it is called "Paak." Prepared with lukewarm water, it is called Seu. Travellers often carry the "Paak" ready made in skins, and eat it as they go along, but if it is possible to get fuel, they prefer making a jorum of tea, and having the paak warm and fresh. The Thibetans are great eaters when they are in plenty. Tea is drunk at all houses, and at every meal, and is regularly used four times a day, i.e. in the morning early, about 8 A. M., at noon, and in the evening. For breakfast which is always eaten at daylight and before washing of hands, face or mouth, the favourite dish is Tookpa, a sort of broth, made with mutton or yak's flesh, Champa, dry curds, butter, salt and turnips. This is eaten without bread, and followed by a cup of scalding tea. They never drink tea when it is the least cold, and if a foreigner allows his cup to cool and then drinks it, he is considered a very careless fellow. An attendant is always on the watch when tea is being served, and as you proceed, he replenishes your cup with a ladle or from the hot teapot until you cry "Hold, enough," or empty out your cup, and put it in the breast of your cloak, the usual receptacle of many necessaries to a Bhotia. The snuff bottle, thick

## THIBET.

woollen nose cloth, tea cup, bits of dried flesh, &c., are all huddled here, without remorse, and it is a most filthy receptacle.

*Salts, Minerals, Metals, &c.*

1st. *Pen*, a carbonate of soda, is found all over Dingham and Thibet, south of the Yaroo; it appears as a whitish powder on the surface of the soil, never in masses under ground. It is not used to make soap or otherwise in the arts, a small quantity is always put into the water with tea; it is considered to improve the flavour, and it gives a high brown colour to the decoction. It is generally used in medicine.

2nd. *Chulla*, Borax. I cannot learn that borax is produced in any part of Thibet south of the Yaroo river. The general direction of the Yaroo is easterly. It is largely imported into Digarchi, whence it is distributed to other parts of Thibet and to India via Nipal, Sikim and Bootan, whence it finds its way to Calcutta and Europe.

3rd. *Sicha*, Saltpetre, is produced generally in Thibet and manufactured at the large sheep-folds where composts of sheep's dung and earth are formed to produce it.

4th. *Moghée*, Sulphur, is not found in Thibet. India exports this article for consumption at Lassa where gunpowder of good quality is made. The charcoal of the poplar (*changma*), and of the willow (*langma*), are considered the best for gunpowder, and this is fortunate, as these two trees alone attain to any magnitude near Lassa.

5th. *Lencha*, common Salt. Three sorts are known in commerce.

1. *Sercha*—White and best.
2. *Chàma*—Reddish and good.
3. *Pencha*—Yellowish and bad, contains soda or magnesia and earthy matter.

All the salt consumed in eastern Thibet is the produce of lakes or mines situated to the north of the Yaroo river, or comes from "Lache", a district lying between Digarchi and Ladak, which is traversed by the Yaroo. The best information procurable is to the effect that all the salt of Thibet is the produce of lakes; still there are people who assert that it is also dug out of the ground. Possibly this is confined to the vicinity of the lakes or to their dried margins. All travellers in Thibet are agreed that the salt-producing districts are the most rugged and inaccessible that can be imagined. It is quite true that men and sheep only can reach the salt deposits. It is also true that the elevation of the deposits prevents their being worked, except for the warmer half of the year, April to November. Thousands of sheep are employed in carrying the salt from the deposits to places accessible to yaks. These latter animals carry it all over Thibet in loads up to 160 lbs. Sheep in open places will carry 20 to 24 lbs.: in the vicinity of the deposits the ruggedness is so great

## THIBET.

that eight to ten lbs. is as much as can be safely put upon them.

Snow falls annually after November in the Salt-producing tracts and covers the ground for two months or more. The elevation of these places cannot, I believe, be under 22,000 feet.

At Digarchi, 1st quality, 2 Rs. per maund, or 20 lbs. for 1 shilling.

At Giangtchi, 20 per cent, dearer. At Lassa, 5 Rupees per maund, or 8 lbs. for 1 shilling.

These prices indicate the relative distances of the places named from the salt districts. There are no available means of ascertaining the actual distances. Digarchi, the nearest mart, may be twenty days' journey on horseback from the nearest salt lakes. See annexed Route No. 1 of 55 marches for loaded men. (p. 334.)

It is believed that salt is now in course of being deposited in a lake at Tiuke in Dingham—near one of the sources of the Arun river, but it is not worked, and great pains are taken to conceal the fact, as there is a prophecy that whenever salt shall be found in the lakes of Dingham, the glories of Thibet shall be on the wane; which means that a rush shall be made from all sides for the salt which will render the exclusion of strangers ineffectual. Salt is given to sheep and cattle in Thibet, but not to horses.

6th. *Doh so*, in the Thibetan language means "stone charcoal." Coal is nowhere found in Thibet. It is known in that country as a produce of China which is seen at Siling, and other marts on the Thibetan confines of China.

7th. *Ser*, Gold; is found in the sands of a feeder of the Yaroo which joins it on the northern bank. The name of this river is not known to me, but it flows from a country called "Shapduk" and falls into the Yaroo to the west of Digarchi. The greater part of the gold of Thibet is the produce of mines or diggings. See Route No. 2 from Digarchi annexed (p. 834.) The Yaroo itself does not yield any gold-washings. There are no mines of iron, silver, copper, quicksilver or lead in Thibet. All these metals, and their oxides are imported from China.

8th. The yellow Arsenic of commerce is found at Teloongchurfoo, near the borders of China to the North and West of Lassa; it is called Pabea.

9th. *Peu-she*, Amber. The Thibetans always wear large opaque amber-like beads in their necklaces; but the substance is not a produce of their own country, nor is it amber; it is, I believe, expissated turpentine-gunda feroza, mixed with some hardening material. Friction makes it smell of turpentine. It is brought from Siling and other marts of China.

10th. Turquoise, *Gya yeu*, or China stone.

*Pe yeu*, Thibetan stone.

*Te yeu*, Cashmere stone.

This beautiful stone is greatly prized in Thibet, and every one wears it, real or imitation, in rings, necklaces, earrings and amulet cases. The

## THIBET.

best are very rare, and although found in Thibet, I believe, no one can give an intelligible account of the localities. I do not believe that the turquoise is a natural product of Thibet, and the following story corroborates the opinion.

"A great merchant of Thibet named Chongpo who traded, ages ago, with India and once crossed the seas beyond India, brought the finest real turquoise to his native country. From that time the stone has been known there, and like coined money, it continues to circulate in the country as a medium of exchange." The imitations brought from China are made of common earthen-coloured or other compositions. They are easily detected. Those imported via Cashmere are real stones but not valuable. Their only test of a real stone is to make a fowl swallow it; if real it will pass through unchanged.

*Route to the Salt Mines in Thibet.* Digarchi to Punchooling 3 marches. Direction at Digarchi N. W. across the Yaroo.

Amringjong,.....	4 marches.	Direction, N. W.
To Nackchang,.....	8	do. N. W.
Sang-zang Lhoda,..	6	do. N. W.
Sakojong,.....	7	do. N. W.
To-then,.....	8	do. N. W.
Bomet,.....	3	do. N.
Lon-kurqun,.....	10	do. N.
Tarokchan,.....	2	do. N.
Borgpagege,.....	3	do. N.
To Salt mines,.....	1	do. N.

Being 55 marches for loaded men, each 10 miles, say 550 miles.

*Route to the Gold diggings.* The same from Digarchi as to the Salt mines as far as Sang-zang Lhoda, thence to Kasha 10 marches, N. by W. To Komunk 5 ditto, N.

Two more marches to Gold diggings, N.

These marches are somewhat longer than the former ones, and may be each 12 to 15 miles.

### ANIMALS.

*The Goa*—An antelope.

*Gnow*—The ovis ammon.

*Rigong*—Hare.

*Kiang*—Wild ass.

*Lawa*—Musk deer.

*Shaoo*—A large deer, *Cervus affinis* vel. Wallichii.

*Cheu* or *Chiru*—Antelope Hodgsoni.

*Dong*—The wild yak of Thibet. The fiercest of all known ruminants. It will rarely allow a man to escape alive if it can come up with him. It is generally hunted on horseback, the great aim being to detach one from the herd. It affects open grassy places and goes in large herds. The following is the plan adopted by hunters on foot for killing the "Dong."

Its favourite pasturages are ascertained, and in the midst of these the hunters throw up circular enclosures of stone a few yards apart, the hunter taking up a position in one of them. When a "Dong" is within shot, the hunter

## THIBET.

having fired at him, instantly quits his enclosure for another; for as soon as the animal hears the shot, whether he has been hit or not, he, guided by the smoke of the discharge, rushes furiously on the enclosure, and commences knocking it to pieces. When the hunter gets another shot at him he retires again from his shelter to a fresh enclosure, and so on, till he has killed his game. The ordinary size of the "Dong" is four times that of the domestic yak, it is black all over, having occasionally a white streak in the forehead. The horns of a full grown Bull are said to be three feet long, and the circumference must be immense. The common mode of describing it is to throw out the elbow, bring the fingers to the ribs and point to the circle thus formed as the size of the base. It is used by the grandees of Thibet at marriages and other feasts, when it is filled with strong drink, and handed round to the company. Nothing more commendatory of the host's joviality can be said, than that "he regaled his guest out of the Dong's horn."

The horns so used are finely polished, and mounted with silver, or gold, and precious stones. If I ever succeed in getting one, I shall certainly present it for a "snuff mull" to the Highland Society, as the days of drinking in horns are over with us now.

It is common in Thibetan goompas—(Lamaserais,) to see a stuffed "Dong" standing in front of the image of Mahá Káli at whose shrine the animal is thus figuratively sacrificed; axes and other instruments of sacrifice are ranged around the image. Strange that Buddhists should preserve *this* feature of Hinduism in their places of worship; not more so however than, as Hue describes, that a Lama should nearly go into fits on seeing a louse from his tunic impaled for the microscope, while the whole of his countrymen and co-religionists are among the greatest slaughterers and consumers of butcher's meat in the world.

*Pegoo*—the yak.

*Cow*—small, like the cow of Bengal. Hair long.

*Sauh*—cross between cow and yak.

*Sauh Yak*—produce of cow by yak bull.

*Ba Sauh*—produce of female yak by bull.

These are great milkers, better than yak or cow; tail half cow, half-yak. Females give young with bulls or yaks, best produce with yaks. Elevation of shoulder less than in the yak. Hair long but less so than the yaks.

*Look*—sheep, four principal varieties; 1st, Chang Look, or Northern sheep, very large with fine wool. Flocks of 400 to 1000 tended by one man;—2nd, Sok Look, rare, but greatly prized; it is a doomba or heavy tailed sheep, comes from the province of Sök situated to the east of Lassa; wool not very fine;—3rd, Lho Look, a very small sheep indeed, generally white, some-

## THIBET.

times black is bred principally about Lassa; wool very fine and like the shawl wool;—4th, Changumpo Look; abundant about Geroo and in Dingcham, generally very large. I never saw finer sheep in my life than all these were; white wool very fine and soft. The flesh of all the Thibet sheep is fine grained and good.

*Peu Ra*—Thibet goat, small, hairy, of all colours. Has an under coat of fine wool, similar to the shawl wool, but there is no shawl wool trade from Eastern Thibet to India at present. Flesh pretty good.

*Phak*—pig, two varieties. The Lho Phak or southern pig which is most abundant to the south of Lassa, and is described as similar to the Indian village pig, and the small China pig now abundant in Lassa and other towns: no wild hogs any where in Thibet. The Chinese butchers in Lassa blow their pork and take in the country folks greatly by its fine appearance.

*Chu*—common fowl, generally small in Thibet, and there is no large kind as in Sikim where the fowls are remarkably large.

*Damjha*—ducks. Not eaten by the Thibetans, but greatly prized by the Chinese, for whose use only they are bred near and in Lassa.

*Damjha Cheemoo*—goose. Not eaten by the Thibetans, but much liked by the Chinese.

*Gang Sir, Gung Kur, Chaloong, Toong Toong*—Comprise the numerous wild fowl, swimmers and waders, which migrate from India in March and April, and return in October and November; they are all eaten, but not extensively. There is a sort of prejudice against killing them; but as they all breed on the lakes and rivers of the country and are most numerous, the eggs are found in great quantities, the people who live by gathering and selling these eggs never rob a nest of all its contents, but take about half the eggs. This forbearance arises from the general aversion to taking life which prevails in Thibet and it has its reward as it is supposed that the birds if entirely deprived of their young, would not again return.

*Chungoo*—a wild dog, reddish colour.

*Koong*—the Civet, is brought from China and inhabits the Chinese borders of Thibet. It is mottled rather than striped.

*Sik*—leopard. Thibet or contiguous countries.

*Tagh*—tiger, do. do.

*Somb*—bear. A red and a black species.

*Nehornehu*—a large sheep, or goat, or antelope. I do not know which is found in the very rugged mountains north of the Yaroo river, and in the neighbourhood of the salt mines or lakes. It is four feet high, has very large horns, sloping back, and four feet long, has a tail 15 inches long, is shaggy, and of various colours, sometimes black and red.

No leeches, mosquitoes or peepsas in Thibet; and maggots or flies are never seen there. There are no bees or wasps in Dingcham or Thibet

## THIBET.

proper. In the valley of Choombi, a good deal of fine honey is found, which is exported to Thibet.

The lakes in Thibet are full of fish, one kind only is described, it grows to the weight of 8 lb.; it is named "choolap," it is not well flavoured or delicate. I have sent specimens of it to the Asiatic Society of Calcutta, and by Dr. Hooker to Sir J. Richardson. Enormous quantities are taken by the hand in the winter season; when the lakes are frozen over, a hole is made in the ice to which the fish immediately rush, and are then pulled out by the hand. Salt is not used to preserve fish, they are gutted, split up, the tail put in the mouth and allowed to dry in the open air, they keep in this way for a year. The principal lakes on this side the Yaroo are Yando Yeumtso, Ramchoo, Kala, and Chomotetoong near Dobta.

*Sheep grazing, &c.* The number of sheep in Thibet is extraordinary. The flocks are immense, and a person of no consequence whatever will have 2,000 or 3,000 sheep. The large owners have as many as 7,000. The fleece is taken once a year in May or June. The ewes breed twice a year. The great lambing season is in April and May. The other in October and November, many of the autumn lambs die from the cold, but this is not considered any great loss as the skins are so valuable. A cloak of lamb skins made of fourteen skins is worth 25 Thibet rupees or 10 East India Company's Rupees.

The rams remain with the ewes always, but after the ewes are in young, the rams have a sort of breeching put on. My informant's notion is, that this is done to prevent annoyance to the pregnant ewes, but I suspect that they are kept in this way, until the proper season for letting them to the ewes. The allowance of rams is two or three for every hundred ewes. The males are gelded when quite young or up to a year old, the prices vary from five to seven Thibet Rupees per head, i.e. two to three rupees of ours.

The Government dues on sheep farms is 10 per cent, in kind, every three years, this is in addition to a general tax of one Rupee per door on all houses per annum.

During the summer season, but little fresh meat is used. The Thibetans do not like to boil it, and are not partial to it raw unless it has been dried. In November there is a great slaughtering in the towns, and a wealthy man in the country will kill two hundred sheep at this time for his year's consumption, the animal is butchered, skinned and gutted, and then placed standing on its feet in a free current of air. It becomes in a couple of days quite hard, and white, and is then ready to eat. It is kept in this way for more than a year, and undergoes great vicissitudes of climate without spoiling. I have seen it at Darjeeling in the rains quite dry and hard, and in no way decomposed. When long

## THIBET.

exposed to the wind of Thibet it becomes so dry that it may be rubbed into powder between the hands. In this state it is mixed with water and drunk, and used in various other ways. The Thibetans eat animal food in endless forms, and a large portion of the people eat nothing else.

The livers of the sheep and other animals are similarly dried or frozen and are much prized. To a person unused to the dried meat of Thibet, the liver is represented as peculiarly distasteful; it is bitter, and nearly as hard as a stone.

The fat is simply dried, packed in the stomachs, and thus sent to market or kept for home use.

The skins furnish clothing for the working classes and servants. All classes in Thibet put on furs of some kind at the commencement of the winter. It is not reckoned reputable to kill your own meat, and therefore every hamlet has its professional butcher. In towns it is a great trade from the enormous quantity of meat consumed. Some butchers will have five hundred carcasses dried and ready at their stalls. The trade of a butcher—Shempa—is hereditary and strange to say a despised one.

The horns of animals are not turned to any useful purpose in Thibet. Small houses are built in the suburbs of Lassa with horns and clay mortar. Goats are also reared in considerable flocks, but principally on account of their milk. The flesh of the sheep is infinitely preferred. The milk of yaks, cows, sheep and goats is used alike for making dried curds, and the various preparations of milk used by these people. The milk of mares does not appear to be used at all in Eastern Thibet although ponies are extensively bred there. The number of other cattle renders it unnecessary. Fowls are of a small breed, and are reared with some difficulty. The large fowls of Sikim and Bootan are much prized there. The Thibetans do not care about fowl as an article of diet, and it is only since the period of the Chinese supremacy that fowls, pigs, or fish have been used by them. Even now in the places remote from Chinese posts pork and fowls are not to be had. The Chinese must have pork, eggs, fowls, and around Lassa, Giangtchi, Digarchi and other places and their stations, these are reared for Chinese consumption.

**Diseases.**—In July and August severe fevers are not uncommon. Cholera is not known; dysentery is, and is often violent, sometimes proving fatal in four days. Cough and diseases of the chest are not prevalent.

Ophthalmia is very prevalent and very severe. Itinerant oculists go about the country and are in good repute: they never perform operations, but cure by application of unguents and washes. Three days travelling in the snow without hair-blinds is sure to produce ophthalmia.

Skin diseases are by no means common, although the people are so filthy in their habits.

## TIN-MINES OF BANKA.

The most dreaded and the most fatal of all diseases is the small pox. The people fly the contagion leaving their homes in the most inclement weather. Inoculation is regularly performed annually in the warmer seasons. Two methods are in use, one by incisions on the wrist, the other is effected by inhalation. A plug of cotton which has been impregnated with small-pox virus and dried is introduced into the nose and left there for two or three days, at the end of which time, symptoms of the small-pox appear. This method was introduced from China where it is largely practised. Dropsy is rather a common disease, and is generally fatal in the cool season. There is very little rheumatism in Thibet proper; at Bakehan in Choombi it prevails to a very great extent. There is a malady called the "Laughing disease" which is much dreaded, people die of it. It consists of violent fits of laughing with excruciating pain in the fauces and throat, men and women have it alike and is named "Joontook" in the language of the country. It frequently proves fatal in a few days, but is not accompanied with fever.—*Journ. Asiatic Society of Bengal, No. CCXVIII. No. 3 of 1855.*

In Tibet the cycle of Jupiter Vrihaspati Chakra, is used. Their epoch occurs in 1025 A.D.

(2891) THIBETAN SACRED BOOKS. Mr. Cosma de Koros mentions that in these, three periods of their compilation are expressly stated, first under Sakya (520 to 638 B.C.), then under Asoka, king of Pataliputra, 110 years after the decease of Sakya; lastly by Kanishka upwards of 400 years after Sakya.—*Prin. Indian Antiq. page 40.*

(2892) TIBELEBU, the name of a tree in Canara and Malabar. It is also named Nambo-gum. The wood is close-grained, and very durable for general purposes in house-building; the carpenters use it generally: a strong, durable wood. It may be procured in Malabar and Canara in quantities, from eight to thirty-six inches in diameter, and from twenty to thirty-five feet long.—*Edye, M. and C.*

(2893) TIMMUE, called also *Taizbul* (of which there are two species). This is a Nepaul plant, yielding a berry resembling black pepper in shape and size. The berry consists of a black or two colored seed, contained in a thin shell or pod, which spontaneously opens when the fruit is ripe. The shell is a large, strong, pleasant spice, used for various culinary purposes, and likewise possesses medicinal virtues. — *Smith's Nepaul.*

District of Marawang.

#### a. Large mines.

Wehing.

Kimsowa.

We proceed to make a few remarks on the mines noted below, of their present condition, productiveness and the number of workmen employed therein, after which we shall point out those situations which offer themselves for new mines.

I. On the Western division: Minto and its neighbourhood was the first part of the Island in which mining was attempted. Soon after the accession of Sultan Mahmud Bahadur-ood-din I. to the throne of Palembang, a large number of Chinese adventurers from this capital, from China, Borneo and the neighbouring islands, opened the ground in every direction, and by an unremitting perseverance and industry, exhausted the richest and most favourably situated spots, after which they directed their attention to new mines, in other districts.

The Malay inhabitants of Minto have participated in the working of the mines and have had severe contentions with the Chinese: according to information of persons engaged in the former works, and communicated by them, about 1000 Ingots (or slabs) might still be obtained annually from the places noted below in the environs of the large mountain. But the Malays are unwilling to undertake the work on the same terms with the Chinese in more productive spots.

The mines of Ràngam have not been regularly worked during the last periods, as the attention of the inhabitants is in a great measure directed to other pursuits, although the mines are not yet

## TIN-MINES OF BANKA.

exhausted. This village consists entirely of Chinese; of 60 male inhabitants, 25 are miners.

The mines of Belo were opened soon after those of Minto

### 2. Small mines.

Jiheng,	Tjungheng,
Beyu,	Samheng,
Hohing,	Samhok,
Suntshiu,	Sunwan,
Bihing,	Kwangya,
Atshiu,	Sinheng or
Sunlie,	Tshengai,

### 3. In the south-east division.

District of Pankal-penang.  
(Here all are small mines.)

Krassak,	Butshak,
Krassak-Ulu,	Tshuntshit,
Bakung-bawa,	Samwey,
Tshapsawun,	Hunseng,
Bankwang,	Tshing-peng,
Henglie,	Tshin,
Kayu-bessie,	Bakung,
Suymouw,	Bulu,
Siema,	Ayer-Udang,
Kwang-tsie,	Gomuru,
Wang-sing,	Pangkul,
Ayer-Mangkok,	Sungie-kurouw.

District of Tirak.

Mines (small) at Tjablang and several other places.

District of Koba.

Koba (and the environs) including Rangouw and Kayu Arro.

District of Poku, and Tubuali.  
Including Nyiry and Ulim.

District of Banko-kutto.

Including Balar, Kabal, Permissang and Selan.

A native of China, Assing, was the first person who introduced a regular mode of mining on Banka. The first mines were worked in the vicinity of the present village in various directions near the southern coast of the island; as the ground was exhausted, the miners gradually retired towards the interior. Two mines are at present worked in this district namely Meng-gelam and Pait Doubang. The former employs 25 miners and is in an improving state, the latter has lately been opened by 13 workmen.

At Palangas 24 Chinese are employed in one considerable mine.

The mines of Tampelang are under no regular discipline at present: they were formerly worked by Chinese and the causes which produced their desertion have been mentioned in the Geographical account. Some tin is annually manufactured by the mountain people; sufficient store of ore is still remaining to encourage the regular mode of mining followed by Chinese. At least 25 miners of this nation might here be profitably employed.

## TIN-MINES OF BANKA.

In the annexed table is estimated the aggregate annual produce of the mines of Rangam, Belo, Palangas and Tampelang, very moderately, at 600 Ingots: and after the mines have been carefully administered some time an increase of this number may be reasonably looked for.

### II. Mines of the northern division.

A. In the western peninsula the mines are dispersed through the districts of Sungie Bulu Mampang, Tenga and Klabbet. The most productive mines in this peninsula are those of Jebus situated in the district of Tenga. They were formerly called the mines of Anten, from the name of the settlement or stockade where the chief resided and whither the product was conveyed. In consequence of the most favourable situation for the intercourse with Palembang the establishment has been removed to Jebus, where a more regular stockade has been constructed.

The miners of Jebus are divided, according to their situation, into those of the Upper and those of the Lower furnace. Of the former, that of Sungie Tango (of the Chinese, Sungie Mentangor of the Natives) is the most important. It employs 42 miners and the ground is very productive. During the last season of smelting (in April &c. 1813), above 200 Ingots were produced from the ore which had been collected in 15 preceding months.

The mine of Suntay employs 25 miners and has produced in the period just mentioned nearly 1000 Ingots. The principal mine of the Lower furnace is at Sungie Balak; here 32 hands are employed, and the ore collected in the same space of time above mentioned was upwards of 1000 Ingots. The mines of Sidm and Taynam, likewise in the district of the Lower furnace, give separately work to 13 miners, but they are conducted with less regularity than the three large mines first enumerated: they are capable of producing if properly administered, collectively, about 1000 Ingots annually.

It may be noted, regarding the mines of this district,

1. That they command a sufficient supply of water from a stream, during the greatest part of the year,

2. That the ground contains, according to all indications, a considerable store of ore, and may be worked for a number of successive years,

3. That a considerable proportion of the miners are married, which has a great effect in fixing them to a particular spot, and making them useful in their profession,

4. That the disposition of the miners is obstinate, highminded and riotous.

In the 10 small mines of this district 29 miners are employed at present: they produce collectively in common periods, 1000 Ingots a year.

## TIN-MINES OF BANKA.

In the district of Kläbbet 2 large and 9 small mines are at present worked : they are all situated in the central part of the western peninsula, within the circumference of a few miles of the Upper-furnace district above mentioned. The first large mine is that of Siuhin : it employs 32 miners and in regard to resources and productiveness resembles the three large mines of the district of Jebus. At a reasonable estimate the annual produce of this mine somewhat exceeds 100 Ingots. The mine of Sannie employs 21 workmen and 500 Ingots at least may annually be expected from it : of the small mines of Blabet, nine in number, several are favourably situated : the aggregate annual produce may at a low rate be calculated at 100 slabs. The large mine of Yunhin is at present neglected in this district. A considerable store of ore is said to be remaining but its depth exceeds that of the other mines, and the extraction of the ore requires, in consequence, an additional expense.

In the district of Sungi-bulu the large mine of Tayu is worked by 28 miners : it is situated near the central mine district of this peninsula, in the neighborhood of the mine of Siam. Besides the two small mines, in which about 7 hands are at work, an attempt has lately been made to open again the neglected mine of Hohin, and a party of workmen has been engaged for this purpose. The aggregate of what may be expected from all these mines, after a liberal calculation, is 1500 Ingots annually, which supposes however, that the attempt of working again the mine of Hohin does not entirely fail, as the two small mines are nearly exhausted.

In the district of Mampang a commencement has lately been made to work several mines. The Kengsy or chief of Belinyu obtained the permission of the Sultan for opening the ground shortly before Banka became a British possession. One of these is a large mine and employs 8 workmen, the other is a small one and is worked by 4. The situation of both, as far as experience has hitherto shewn, is favourable, in regard to the store of ore, and they both command a supply of water : the works have been laid out with judgment, but the settlement labours under the usual disadvantages of new establishments on Banka ; the climate in many situations, especially near the sea, is unwholesome, and the settlement is exposed to the visits of smugglers and pirates. The productiveness of this district will depend in a great degree on the number of miners that can be induced to settle here from other parts of the Island : with those necessary improvements which may soon be expected, this district will yield annually at least 600 Ingots, and a considerable increase will probably follow if the mines are well administered.

In the Eastern peninsula of the northern portion of Banka, the miners are distributed through

## TIN-MINES OF BANKA.

the districts of Belinyu, Lumut, Sugie-liat and Marawang.

The mines of Belinyu were opened soon after those of Belo by a Chinese subject of Palembang named Demang Ko ; and some extensive works were commenced about the same time at Pandjie by a Chinese of the name of Bing ; both were afterwards united and administered by one chief. The only productive mine which is now worked in this district is that of Towallam, it employs 11 miners.

Several small mines have been worked until lately. The mines of this district have for many years been in a declining state. In the year 1805 the average annual produce was 1200 Ingots : this has gradually decreased to about one half of that number. In the mine of Pandjie the labours have been entirely discontinued. In a considerable village established here, 16 miners are remaining, most of whom are married and have directed their attention to other pursuits. They assert that an opportunity remains for opening a new mine a few miles to the eastward of their village.

The present annual produce of Belinyu, rarely exceeds 600 Ingots : what may reasonably be expected from about 30 miners that are now unemployed will be enumerated in the general table.

In the district of Lumut, three large mines are worked, namely Hapsun, Lakuntouw and Keighwad : they are of less extent than the large or Kolong mines of the other districts, and are undertaken by one chief miner, (Kongsy) who engages as many assistants as his works require. The mine of Hapsun employs at present 4 workmen ; that of Lakuntouw 7 and that of Keighwad 5.

The remarks on the declining state of the mines of Belinyu apply equally to this district, and several of the mines formerly worked have been exhausted. According to a statement which was made up from the books of the chief, the annual produce during the last 20 years did on an average not much exceed 400 Ingots.

Through the extensive district of Sungie liat 20 mines are dispersed of which 2 only are large mines : they will generally be enumerated in the table. The mines of this district were first opened by the family of the Chinese Assing above mentioned. His son Demang Dyaya Laxana obtained from the Sultan the privilege of working them about 40 years ago. Since this period the most favourable and productive situations have been successively exhausted and the produce has gradually decreased. The average number of Ingots which may be expected annually from these mines collectively at present is 2600. This calculation supposes that the district of Ieniang, which has been less worked than other parts, is carefully administered, and that a large mine

## TIN-MINES OF BANKA.

lately opened near the stockade will answer the expectations that have been formed of it.

In the district of Marawang 15 mines are worked, of which 2 are large mines. One employs 10 workmen and produces on an average 300 Ingots annually, the other was formerly neglected in consequence of bad management. Thirty miners have lately united to work it again, and have made some progress: the investigations that have been made indicate a store of ore, and the increase of the annual produce of Marawang will depend, in a great measure, on this mine. Of the small mines, 6 are in a favourable state and according to moderate calculation will yield annually 800 Ingots; the others are nearly exhausted or want the necessary supply of water. I have estimated the annual produce of this district at 1500 Ingots.

### III. Mines in the third or south-east division.

In the south east division of the island I have visited only the districts of Pangkal-pinang and Tirak. The former is, next to Jebus and Sungieliat, the most important and productive portion of Banka. It contains at present 18 mines dispersed through the subdivisions of Messu, Bakung, Kayu-Bessie, Ayer maukok and Bangkwang in which 63 miners are employed. Although the districts in which these mines are situated have been worked nearly thirty successive years, they still contain a considerable store of ore. It is supposed by the best informed persons that, with a careful superintendence of the mines and the necessary direction of the labours of the miners the aggregate annual produce will amount agreeably to a moderate computation to 4000 Ingots.

The mines of Tirak were formerly under the superintendence of the chief of Marawang: and have been opened within the last 10 years. They have during several seasons been neglected, but if properly administered the former annual product of 400 Ingots may be expected from them again.

Before I enumerate the districts next in order in this division of the Island which supported mines in former periods, I shall mention Tubuali near the extremity. This district, although it has greatly participated in the common disasters of this part of Banka, (which will be detailed in another place) has not like most others been completely ruined and depopulated. In Tubuali the chief business of mining has hitherto been carried on by the mountain people; but a number of Chinese miners have lately been introduced, a regular mode of mining is attempted, and an increase may soon be expected in its produce. Considerable improvements are however still to be made, and a large additional number of Chinese miners can be employed with advantage. Much of the future produce of the Island must be expected from this and from the neighbouring districts.

## TIN-MINES OF BANKA.

I have estimated the annual produce of Tubuali including Nyiry and Ulim at present, at 1000 Ingots. The latest accounts of the former annual produce do not indeed amount to that number, but as the business has hitherto been carried on very imperfectly by mountain people alone, I have taken into consideration the introduction of the Chinese and the general improvement and extension of the process of mining. The additional quantity (above the 1000 Ingots mentioned) to be expected in future from Tubuali will be stated below.

I proceed next to mention those districts in which from various causes, but principally on account of the attacks and ravages of the pirates, the mines have been entirely neglected or deserted.

At the southern boundary of Pangkal-pinang, we meet with Koba, which was formerly one of the most productive districts of Banka. It supported 22 years ago Chinese miners who worked 15 mines, and produced annually upwards of 3,000 Ingots: It includes the sub-divisions of Rangouw and Kayu-Ano, along the eastern coast of the island, while Pangkul and Sungie Kurouw are generally added to the district of Pangkal-pinang. Paku is situated near the centre of the island in a direction west to Koba: although the inhabitants of this district paid more attention to the preparation of Iron from the ones of the neighbourhood, a small quantity of Tin was also manufactured. In the estimate of what may reasonably be expected from those various mines, I have calculated Koba, including Rangnouw, Kayu-Aro, and Paku in the first periods at 1250 Ingots annually, provided a sufficient number of Chinese miners can be induced or encouraged to settle there and to recommence the working of the mines. More than double that number may be expected in a few years, after the works have been extended according to the opportunities afforded by productive beds for collecting ore.

The district of Banko-kutto takes in the long range of Permissang hills, in the environs of which various mines were formerly worked. These were dispersed through the sub-divisions of Balar, Kabal, Permissang and Selan, in all which a very inconsiderable portion of a formerly extensive population is now remaining. It will therefore require time and care to derive those advantages from them, which they are capable of affording. From the most credible information which I have been able to obtain, I have estimated the annual produce of those districts collectively, provided the necessary miners can be introduced, at 500 Ingots; which number may be expected to increase as the progress of the settlement advances.

In taking a review of the Island of Banka it will appear that most of the larger districts have already supported an establishment; and although the greatest part of the

## TIN-MINES OF BANKA.

is now deserted and waste, it formerly possessed an extensive population and very considerable mines. It is evident therefore any new situation for a mine, will be comprised in, or at least adjoining to, one or other of the districts already enumerated, for the general limits and extent of which I refer to the map.

In my enquiries after favourable spots for new mines in which the original store contained in the earth, might have been exposed to observation or extraction, the following places were particularly pointed out to me :

- |            |                 |
|------------|-----------------|
| 1. Dshebu. | 3. Tengkiya and |
| 2. Mapur.  | 4. Keppu.       |

The river of Dshebu passes several miles to the northward of the stockade of Klabbet; and its neighbourhood, near the confines of the large mining district, is supposed by well informed persons to afford an opportunity for opening a large mine of considerable extent, and in my estimate of an additional produce from the district of Klabbet, as well as of new miners to be introduced, I have taken this into consideration.

In the district of Mapur, included between Lumut in the west, and the northern parts of Sungie liat in the east, an attempt is made at the present period to resume a former attempt which was frustrated by the pirates. A number of Chinese miners have associated for this purpose : the condition of the strata, as far as regards a store of ore is reported to be favourable but the neighbouring country is almost a complete desert, only a small part of the former population of mountain people is remaining, and the settlement will require considerable time to recover. In my calculation I have estimated the produce which will probably be afforded when the works have been properly effected, at 500 Ingots annually, which number may be expected to increase from year to year. But no part of the Island is supposed to contain a richer store of ores than the districts of Tengkiya and Keppu, at the southern extremity of the Island, forming part of the larger district of Tubuali. Keppu is situated on a river of the same name, which discharges itself into the straits of Lipar, and Tengkiya lies not a great distance further east.

As long as Banka was exposed to the perpetual attacks of the pirates, no person ventured to form an establishment in a part so exposed and distant ; but under the present government and administration, the attention is most strongly directed to these two districts : their situation is not distant from Tubuali, and they may be probably superintended by one person.

In making an estimate of the probable produce from Tengkiya and Keppu, I can be guided alone by the information obtained from others. I have procured a statement from several intelligent Malays at Minto, (natives of Palembang) as well as from various Chinese at Pangkal-pinang who were formerly employed in the mines of the

## TIN-MINES OF BANKA.

southern part of the Island, according to which each of these districts will be able to furnish, by the regular process of mining carried on by the Chinese, annually 1,000 Ingots, and a very considerable increase of this number may be expected when the population and an additional number of Chinese miners, admits of a proportionate extension of the mines.

I shall add a few remarks as to an increase of the produce of those districts which now support the principal mines.

Although the mines in the northern division are at present more extensively worked than those of any other part of the Island, they still admit of an increase, which, in the table annexed, I have estimated as follows viz.

In Jebus annually,	... 1200 Ingots
„ Klabbet (including Dshebu.)..	1250 „
„ Sungie bala (taking in a new mine lately attempted towards point Tanjong-Tamudsha)..	250 „

In Mampang (including an additional large mine) 500 Ingots. As to the mines of the eastern peninsula, if new works are undertaken by the miners of Panje, I have calculated an annual increase of the produce of Belinyu of 500 Ingots, while in Marawang a small increase only may be expected, probably not exceeding 250 Ingots.

The mines of Sungie-liat are already worked to their full extent.

In the district of Pangkal-pinang various new mines may advantageously be attempted, while the present works may be extended, particularly in the subdivisions of Bakung, Bulu, Ayer-Udang and Gomuru : the deserted mines of Pangkul and Sungie-Kurouw may also be worked again with favourable prospects ; and in conformity to these opportunities I have formed the estimate of an increase, to the general amount of 2000 Ingots. The number of fresh hands required for these new or additional mines is also included in the general table.

From the statements above detailed, the order of the importance and productiveness of the mining districts of Banka is as follows :

- |                   |                 |
|-------------------|-----------------|
| 1. Jebus          | 5. Marawang.    |
| 2. Pangkal-pinang | 6. Sungie-bulu. |
| 3. Sungie-liat.   | 7. Blinyu.      |
| 4. Klabbet.       | 8. Lumut.       |

I have not included in this statement Mampang, Tabuali and the mines eastward of Minto to Tampelang, as their supplies depend more than in the other cases on accidental circumstances.

It appears from the annexed table, shewing the quantity of Tin produced on an average annually at the present period that the number of Ingots amounts to 21,600 yielding according to the usual mode of estimation 10,800 piculs of 100 Catties Chinese weight or 133½ lbs. Troy each, or 1,440,000, lbs. It would be interesting in various points of view, to trace for a number of ascending years, the annual produce

## TIN-MINES OF BANKA.

of the mines of Banka, but for this purpose, no records are left on the Island, and we have only the verbal accounts and relations of the old inhabitants to supply us information: these are, however, confirmed by the testimony of many respectable persons at Palembang and at Batavia, as well as by various documents which remain at the latter place. They tend to prove that the former produce of Banka exceeds that of the present time in a manifold proportion.

The most prosperous period of the Island both regarding the supplies obtained from the mines and the general condition of the Inhabitants, was during the reign of Sultan Achmad Nadga Mudin I, and some time before his accession to the throne, or between the years 1750 and 1775. Sixty thousand piculs, or 120,000 Ingots, is but a moderate estimate of the aggregate produce of the mines during this period, and by most persons supposed to be competent to afford information on the subject, it is rated much greater.

In the year 1770, May 11th, the Governor and Council at Batavia published the following Resolution:—"Not to accept from Palembang annually, more than 25,000 piculs of Tin: and because this year 5000 piculs above this quantity have been sent here, no more than 20,000 piculs shall, on any account, be accepted the following year: of which timely information shall be sent to the king."

The operation of measures of this kind requires no comment; the clandestine trade to China, which was facilitated by the annual visits of numerous junks and already engrossed at least one half of the produce of the mines, received not only encouragement but sanction, as the only support of the numerous miners occupied on Banka, depended on a ready disposal of the manufactured Tin; and it is adduced at present to afford a testimony of the productiveness of Banka at this time.

Two causes have principally contributed to produce the egregious defection in the annual proceeds of the Island.

1. An actual diminution of the store of ore, the gradual exhaustion of the mines in the neighbourhood of the ancient settlement; and

2. The concurrence of the various disasters which have harassed Banka since the year 1784. The latter will, with more propriety be detailed in another place, on the former I shall add a few remarks.

The period of the discovery of the Tin-mines on Banka is not very remote; it falls within the first 20 years of the last century, and this (as has already been noticed) shortly preceded the settlement of Minto. During the first year of the reign of Sultan Mahmud Badur-Udin I, attracted by the prospect of gain, numerous Chinese miners and adventurers resorted to Banka (as above related,) about this time, and as the stores of ore near the first establishment failed gradually at-

## TIN-MINES OF BANKA.

tempted and removed to other districts, spreading successively through Below, Klabbet, Sungie-liat, Anten or Jebus, Pangkal-pinang, Marawang and Sungie-bulu, selecting the most favourable spots where a rich store of ore combined with a supply of water to facilitate the labours of the miners.

After a lapse of about 30 to 40 years a gradual diminution was observed in many parts of these districts, while others were entirely exhausted and new situations attempted: but still the aggregate annual produce of the Island amounted nearly to the quantity above stated. Since the year 1780, a decrease has become more evident, and after the commencement of the disasters of the Island 30,000 piculs were rarely produced in one year. During the last 15 years the annual quantity has gradually lessened. The constitution of the mines elucidates this diminution in a great degree, the ore is uniformly deposited in horizontal beds at no great distance below the surface. These beds have in some instances been immensely productive; by which the abundant supplies of former times are accounted for, when the number of miners was proportionate to the opportunities afforded of collecting ore. The inquisitive shrewdness of the Chinese directed them to the most profitable spots, and in travelling through the western and the northern division of the Island, one passes extensive surfaces which have been turned up and drained of their contents, exhibiting the remains of former mines and aqueducts.

But, although in the western and in the northern divisions of Banka, the most productive situations have been exhausted, or their store considerably diminished, yet the annual quantities computed as the present produce of the various mines above mentioned (and which are exhibited in the table) may with little variation be expected, as far as my most careful observations have enabled me to judge, and after the establishment of the new mines of Mapur, Dshebu, Mampang, Pandjie, &c., and particularly when the great south-east division is brought into activity and the mines of Koba, Rangow, Kayu-Ano, Tengkiya, Kappa, Selan, Permissang, Banko-kutto &c., contribute their proportion, the full quantity stated in the table may be expected: this according to my personal calculations and enquiries, assisted by the concurrent testimony of well informed persons, must however, be considered as the maximum to be expected from the mines of Banka for the next five years, and probably for a longer period, requiring for its production the advantages of a careful administration.

In the future regulation of the affairs of Banka it will become an object of primary policy and interest to investigate experimentally those tracts which have in a great measure remained untouched, in order, as the beds near the present establishments are exhausted, to remove them to

## TODAH.

to new situations in those districts which contain a larger store of ore.

To these remarks, I shall only add a few documents which were afforded me by the books of the Kongsies (or chiefs of the mines) as to the annual produce in the following districts for a small number of successive years.

### *The mines of Jebus produced.*

As to the annexed table, shewing the quantity of Tin produced on Banka, I shall only observe, that most of it is compiled from inquiries on the spot, and from a personal inspection of more of the mines during a journey through the Island, to which has been added whatever information or instruction could be obtained from intelligent natives, and from the books and annotations of the Kongsies or administrators of the mines during the sovereignty of Palembang.—*Horsefield on the Tin of Banca. Journ. of the Ind. Archi Vol. ii. No. XII. December 1848, pages 796 to 809.*

(2896) TODAH, Kotah, Badaga and Kurumbu, are names of aboriginal tribes occupying the Neilgherry hills. The dialects spoken by them differ chiefly in the pronunciation, therefore, the same or nearly the same word in the

## TORTOISES.

month of a Todah, with his pectoral pronunciation, can scarcely be recognized as the same in the month of the Kotahs, with their dental pronunciation. The Badaga and Kurumbu dialects are midway between the former two, with regard to pronunciation. Amongst the several Badaga tribes, those who came at a later period to the hills, the "Kangaru" (Lingaites), for instance, who emigrated from Targuru, speak a purer Canarese than the common Badaga.

The names of the five Todah Tribes are Peikee, which is the chief tribe, Kenna, Pekkan, Kuttan, Todi.

They are idle, dirty, intemperate and unchaste. Polyandry has always existed among them, and their women are now addicted to general prostitution with men of other races.—*Page 8, Beng. As. Soc. Jour. 1856 and No. 6 of 1838.*

(2897) TODDALIA ACULEATA is a common bush on the Coromandel coast. All the parts are very pungent, especially the roots when fresh cut. The fresh leaves are eaten raw for pains in the bowels; the ripe berries are fully as hot as black pepper, and have nearly the same kind of pungency.

The fresh bark of the root is administered by the Telinga physicians for the cure of the remittent, called Hill fever. Roxburgh conceived that this tree possessed very valuable stimulant properties, and Dr. O'Shaughnessy is of the same opinion, though he does not appear to have ever made any experiment with it. In fact nothing has been added to what Roxburgh knew, although some specimens of the bark were sent to Europe in 1818. Its properties are worthy of further investigation.—*Ind. Ann. Med. Sci. for April 1856. p. 395.*

(2898) TORTOISES. In Southern Asia, are found a very considerable number of fresh water Tortoises. Testudo Greca inhabits a part of Syria, the Test. geometrica, an African species, is found also in the island of Ceylon; but the existence of the Test. Indica in a natural state upon the coast of Coromandel, is not confirmed. Of the known species of Trionyx, several inhabit the rivers of Southern Asia. One has been observed in the Euphrates, which is perhaps identical with the Trionyx of the Nile, also found in Hindustan. The Ganges maintains the Tr. Gangeticus, peculiar, as far as is known, to that river; another, the Tr. granosus, which forms the passage to the Emydes, is found also on the coast of Coromandel; while two others, Tr. stellatus, and subplanus, have been observed from Bengal to the Island of Java. The Trionyx of Japan belongs most probably to the first of these, which would thus be nearly as widely diffused as the E. vulgaris of which a local variety is found in the Islands of that Empire. The other Emydes of the South-eastern portion of Asia are E. Tectum; E. megacephala, so characteristic in its heavy or unwieldy form; E. Te-

## TORTOISESHELL OF CELEBES.

trionyx, intermediate between the Emydes and Trionyx, and a native of the river Irawaddy; E. Spengleri, of which several interesting varieties are known from the isle of France, Ceylon, Penang, Malacca, Sumatra, Java, Borneo, and China; and finally, two species, which vary from the others by their rounded shell, and of which one possesses a moveable sternum; E. couro inhabits China, the southern point of Celebes, and the island of Penang, Java, and Amboyna; while the other, E. trijuga, has only been found in Java. (*Siebold, Faun. Jap. Chelonii per C. J. Temminck, and H. Schlegel*) Magazine of Zoology and Botany V. 1. pp. 199, 200.

### (2899) TORTOISESHELL OF CELEBES.

Amongst the more valuable of the commodities which the enterprising and industrious Bugis annually bring from Celebes and other eastern islands, Tortoiseshell holds one of the first places. The quantity imported into Singapore sometimes rises above 13,000 and sometimes sinks below 7,000 pounds, but the average one year with another is about 10,000 pounds. The following is an account by Mr. Vosmaer of its collection by the Orang Bajo of the south eastern peninsula of Celebes.

The Orang Bajo distinguish four principal kinds of Tortoise, and name them Kulitan, Akung, Boko, and Ratu. The first named is the kind, which on account of its costly shell, is the most prized. It is the so named Karet tortoise. The shell or back of this creature is covered with 13 shields or blades, which lie regularly on each other in the manner of scales, five on the middle of the back and four on the sides; these are the plates which furnish such costly tortoise shell to art. The edge of the scale or of the back is further covered with 25 thin pieces joined to each other, which in commerce are known under the appellation of feet or noses of the tortoise.

The value of the tortoise shell depends on the weight and quality of each head, under which expression is understood the collective tortoiseshell belonging to one and the same animal, which is the article of commerce so much in request both for the Chinese and European markets.

Tortoise-shells which have white and black spots that touch each other, and are as much as possible similar on both sides of the blade, are, in the eyes of the Chinese, much finer, and are on that account more greedily monopolized by them, than those which want this peculiarity and are on the contrary reddish, more damasked than spotted, possess little white, or whose colours, according to their taste, are badly distributed. The caprice of the Chinese makes them sometimes value single heads at unheard of prices, namely such as pass under the name of white heads, which they also distinguish by peculiar names. It is almost impossible to give an accurate description of these kinds, and of their subdivisions, for these depend on many circum-

## TORTOISESHELL OF CELEBES.

stances which remain inappreciable to our eyes. It is therefore enough to remark on this subject that such heads, as, possessing the above named qualities, are very white on the blades and have the outerrim of each blade to the breadth of 2 or 3 fingers wholly white, and the weight of which amounts to  $2\frac{1}{2}$  catties (qualities which are seldom found united) may be valued at one thousand guilders and upwards. The feet of the tortoiseshell are only destined for the Chinese market; whenever the two hinder pieces are sound and have the weight of  $\frac{1}{4}$  catty or thereabouts, which is very seldom the case, they may reach the value of fifty guilders and more. The whole shell of a tortoise seldom weighs more than 3 catties, notwithstanding it is asserted that there sometimes occur heads of 4 and 5 catties. Tortoise shells are also sometimes found, of which the shell, instead of 13 blades, consists of a single undivided blade; the Orang Bajos call this kind, which very seldom occurs, Lojong.

The Akung also furnishes tortoise shell (karet,) but the shell being thin, and of a poor quality, much less value is attached to it.

The Boko is the same as that which is called Panju by the Malays. It is the common sea-tortoise which is of no other use than to be eaten. To these sorts the Panjubui ought to be added, being the common tortoise, with a thick shell, like that of the proper tortoise, but of poor quality and therefore of trifling value; so also the Akung Boko which is distinguished from the common Boko by its much larger head.

The Ratú, lastly, furnishes a sort which is distinguished by its peculiarly great size, the Orang Bajos asserting that it is usually twice as big as the largest tortoise-shell tortoise, and therefore 5 to 6 feet long and even more.

The usual modes by which the Orang Bajos catch the tortoise, are principally by the hadung, the harpoon and the net; to these we add the simplest of all, namely, falling upon the females when they resort to the strand to lay their eggs. This is also the most usual, I may almost say the only way, by which the inhabitants of the coast catch this animal. They need nothing more, than, as soon as they have got the creature in their power, to turn it on its back, when, unable to recover itself it remains lying helpless in their power. It sometimes also falls into the hands of the dwellers on the coast through means of their fishing stakes, into which it enters like the fish, and from which it can find no outlet but remains imprisoned in the innermost chamber.

Whenever the Orang Bajos have caught a tortoise, they kill it immediately, by blows upon the head. They then take its upper shield or the back itself quite off, being the only thing about the animal which has value. The tortoiseshell adhering so fast to the shield that, if they at once pulled it off, there would be danger

## TRIMURTI.

of tearing the shells, they usually wait three days, during which time the soft parts become decomposed and the shells are loosened with little trouble. When they wish to remove the shell immediately after the capture, they separate it by means of boiling water. They also often accomplish this object by the heat of a fire, in the application of which, however, a danger is run of injuring the shell by burning it, for which reason this mode is only adopted by those who do not know its value.—*Journ. of the Ind. Archipel. Vol. III. No. 17. June, 1849.*

One of these Topes at Manikyala, was opened by General Court, and subsequently explored by General Ventura. One exists at Usman Khatir, in the basin of the Indus and another at Peshawur.

(2900) TOPE. Sepulchral mounds, found in various parts of India, in the caves of Keneri or Kanuri; on the Neilgherry Hills &c. Also the term applied in Southern India to groves of trees, generally of mango or tamarind.

(2901) TOWTAL the Malayala name of a tree which grows to about two feet in diameter, and thirty feet high. It is remarkably light but not very durable, and is used by the natives for catamarans, &c.—*Edye. M and C*

(2902) TRIBULUS TERRESTRIS, LIN.

*Ainslie's Mat. Med. p. 269 and 257.*

(2907) TRIMURTI. The term employed to designate the Triad of gods of the Hindu mythology, Brahma, Vishnu and Siva. Whose attributes are those of the Creator, the Preserver and the Destroyer. The consorts of Brahma are Saraswati, Sakti or Maya. Of Vishnu, Lakshmi, Padma or Sri, and those of Siva are Parvati, Bhawani or Durga. The attendant Vahan or vehical of Brahma, is a Hansa or goose: that of Vishnu is a Garuda or Bird, and Nandi or the Bull pertains to Siva. Meru is the station of Brahma: the sun that of Vishnu, and Jupiter that of Siva. The Symbols of the three deities

## TYPHA ELEPHANTINA.

are respectively • Time, Water and Fire. Their common titles A. U. M. are for Brahma Parameswara, for Vishnu Narayana, and Mahadeva for Siva. Brahma is worshipped mentally, but Vishnu is worshipped under the figure of the Saligram and the nine Avatars, while the Lingam and his million epithets are the figures indicating Siva. Brahma of the Hindu theology is supposed to be the analogue of the Saturn of the West while Jupiter represents Vishnu and Siva.

(2908) TRISUL . . . A trident, the Symbol of Siva once used on a copper paisa weighing 98½ grains for circulation in the province of Benares only.—*Prin. Ind. Ant.*

(2909) TUBA of Mindoro or Tuac of Timor and the Moluccas, the sap of a palm, converted by distillation or fermentation into spirit or vinegar.

(2910) TUKBEER, Arab. The Mahomadan creed.

(2911) TULIPA STELLATA.

Lallee waroon, HIND	Nulkia, HIND.
Myhoula, „	

It is abundant in the Kangra valley and the Kemaon Hills, whence its bulbs, which are edible are exported.

(2912) TUMONGONG, amongst the malays, a high officer of State, to whom the superintendence of internal police matters is entrusted.—*Journ. Ind. Arch. No. IX. Vol. V. p. 568.*

(2913) TURANIAN TONGUES. Amongst these are the Naga, Dhimali, Hayu Kuswar, Kirauti, Limbu, Chepang, and Bhramu, of which the first is Indo Chinese, and the rest Himalayan, all belong to the pronominalized class.—*Mr. Hodgson No. 6 of 1856 of Beng. As. Soc. Journ.*

(2914) TUS or TUZ, a Birch bark, which, in addition to leather, we learn that the ancient Persians wrote upon. The same seems to have been anciently used in the North India also. In Huen Thsang's time the early Buddhist scriptures of Kasyapa's Council were written on the leaves of the Tala palm. In the eleventh century, according to Alburini, paper was used; in the south of India the leaves of the Tari were used, but in the provinces of Central and Northern India, they used the inner bark of a tree called tuz. And it was the branch, of a tree of the same kind called Bhoj, with which they covered their vessels.—*V. 2. p. 46.*

(2915) TUWA or TAWA, HIND. An iron girdle on which cakes are baked.

(2916) TWASHTRI, the vulcan of Hindu mythology.

(2917) TYE TINCO, the refuse of opium, used by the poorest Chinese in Singapore.

(2918) TYPHA ELEPHANTINA.  
Patera, HIND. | Pudera, HIND.

Leaves useful in making mats.

## U.

(2919) UKROT; The walnut of Chittong is reckoned the best of any produced in the Nepaul territories; but those of Tibet are esteemed superior. The shell of the Chittong, and indeed of most of the Nepaul walnuts, is remarkably hard. The wood is employed in the manufacture of gun stocks. The best charcoal is made of the Bhâng or holly leaved oak.

(2920) UNONA DISCOLOR. Teling Chelkadoooga : Atamaram.—*Rheed.*

A pretty large tree, a native of the mountainous parts of the Northern Circars and of Chittong. The wood is employed for various economical purposes but chiefly for rafters.—*Roxb. Rhode. M. S. S.*

(2921) UPANGAS. Of these, there are four,  
1 Purana, or History comprising the 18 Puranas.  
2 Nyaya, Logic and the principles of knowledge.  
3 Mimansa, Religious Principles and duties.  
4 Dharma Shastra, Law, Human and Divine.

(2922) UPANISHADS. The whole number of Upanishads known at present, is 138, of which only 11 have been published. According to the theory laid down in the Mahavakya Ratnavali, there are 1,180 Upanishads equal to the number of Vedaic schools, one Upanishad belonging to every school. This theory however is fanciful. According to the received definition, the Upanishads are such parts of the Vedas as embody their metaphysical and theological views which may be compressed into the formula that the finite soul is essentially the same with the infinite spirit or Brahma and though the various

Upanishads widely differ from each other, all maintain this identity of the finite and infinite spirit. Dr. Weber arranges the Upanishads into (1) those which belong to the three first Vedas, as forming the Vedanta system; (2) those comprising all the Atharva Upanishads and referring to the Vedanta system in its entire development; (3) the Upanishads in which the meditation has become crystallised and is limited to the mystical word "Aum," (4) those treating on the order of the "Sunnyasi" and (5) the last division which includes the sectarian Upanishads, in which the Atman is worshipped as an independent deity.—*Thomas Prinsep.*

(2923) UPAVEDAS. Of these, there are four, the Ayush, Medicine; Gandhurva, Music; the Dhanush, Warfare; and the Sthapatya, Mechanics.—*Thomas Prinsep.*

(2924) UPPUTAH, the Malayala name of a wood which is hard, strong, and heavy. It grows to about twelve feet high and ten inches in diameter. It is used by the Native carpenters for the frames of boats, of coasting vessels, and similar purposes, where strength is required.—*Edye, M. & C.*

(2925) UQEEQA, ARAB. A sacrificial rite, consisting of an offering to God, amongst the Mahomedans, on the Chutthee or Chillah, of one if a girl or two he goats if a boy.—*Herk.*

(2926) URSUS SEWALENSIS. A fossil bear, discovered by Sir P. T. Cautley in the Sewalik Hills.

## V.

(2927) VACHY WOOD. Mimosa Flexuosa, *Rottl.*

Vaghaymarum, TAM.

This is the Tamool name of a large tree, the wood of which is brown, and is used for making bullock bandies &c.&c.—*Ains. Mat. Med. p. 208.*

(2928) VALLISNERIA VERTICILLATA.  
Poo-natsoo. TEL.

Grows in clear, standing, sweet water. Flowers during the cold season, and consists of simple, filiform roots, and a number of fine, filiform, jointed shoots, or stems; some creeping, some floating below the surface of the water, branches solitary, axillary.

The Berhampore sugar refiners use this herb, while moist, to cover the surface of their sugars, as clay is used in the West India islands, and in

two or three days the operation is finished exceedingly well.—*Roxburgh's Flora Indica V. 3, p. 751.*

(2929) VALMIKI. It is a current belief, in many parts of India, that the poet Válmíki, the author of the Ramayana, was a *thug* or stranger. This notion was probably derived from a strain put upon some verses, which make out Valmiki to have been, originally, on his own confession, simply a robber. This extract also embraces the received account of the origin of the poet's name.

(2930) VAN. The Lake of Van is about forty miles long, and from twenty to thirty broad. Its waters are salt. It is surrounded by a beautiful outline of mountains, whose tops are covered with perpetual snow. The old ruin-

ed stone-built town of Ardische is situated on a narrow strip of land running into the lake. There are a few soldiers quartered in it. The borders of the lake about it are low and swampy, and abounding in wild fowl and various other kinds of game.

(2931) VANILLA. *V. Aromatica* is said by Martins to yield the true Vanilla, but the best Mexican Vanilla, is the produce of *V. Planifolia*, of which Pereira mentions *V. Sativa* and *V. Sylvestris* as two varieties.

(2932) VARDAGOUR, the Malabar name of a tree which is remarkably hard and strong. It is used by the natives for spears, weapons of defence, and such purposes as require the hardest kinds of wood. This tree is known as a jungle wood only.—*Edye, M. & C.*

(2933) VAW KARAI, the Malabar name of a tree which produces the country olives, to which the natives are very partial. This fruit is also food for the wild beasts and birds of the forest: the tree grows to about eighteen feet high, and twelve inches in diameter.—*Edye, M. & C.*

(2934) VAYNGIE in Tamil, and Mulu-Vengah in Malayala. *Pterocarpus Marsupium*. This tree is of a dark olive and light-brown colour; it is very strong and tough; it sometimes grows crooked, and to about two feet in diameter, and from thirty to thirty-five feet long: it is used by the Natives both for houses and vessels. This sort has a single leaf in the shape of a pear, but the VellaVengah, which is the white or light coloured, has a long leaf, and grows to about eighteen inches in diameter, and twenty feet long. The natives prefer this wood for boat crooks, and the curved parts of the frames of pattamahs and native vessels.—*Edye, M. & C.*

(2935) VEDAS. These are generally considered as four in number, the Rich, the Yajush, the Sama and the Athavarah, but the last of these evidently belongs to a much later age than the rest. The hymns of the Rich Veda are repeated entirely in a disjointed form in the Sama; and, with little alterations in the Atharva, also. While the Yajush contains principally forms of prayer. Portions of the Rig-Veda have been translated by the late F. Rosen, the late M. Langlois, and by Professor Wilson. And Dr. Muller is producing a complete one at the expense of the E. I. Company. The 3000 pages of large quarto which have already appeared, embrace little more than half the Sanhita with Sayanas' Commentary.

The body of Vedic literature is immense. In the Brahmanas, which are considered as belonging to the Vedas, moral precepts, religious instruction and information are conveyed. Professor Wilson supposes them to belong to the 8th century before Christ, and they are said to recognise the institution of caste. Very little is

known of these works, which are less interesting than the Sanhitas as being of later date. The Brahmasutras, the chief authorities of the Pantheistic Vedanta school, though much later than the rest, are still mnemonics, as also the Vaiseshika or atomic school of Kanada.

The language of the Vedas is not Sanscrit in the strictest sense of the term, but there is not sufficient difference between it and classical Sanscrit, to authorise its being called a separate language. The difference is not so great as between Anglo-Saxon and modern English, but it is greater than between Homers and Demosthenes Greek.

Good scholars are of opinion that the Vedic hymns were composed mostly about fifteen centuries before Christ, but not committed to writing and therefore not collected until the eighth century B.C. The geography of these hymns confirms the theory that the Aryan Race migrated from Central Asia about seventeen centuries before Christ, entered India by the North West, dwelt during the earliest Vedic portion in the Punjab, and migrated or rather fought their way into Central India during the five centuries that succeeded.

From the frequent mention of the Sursooty and other rivers, we learn that the Punjab was the locality of the Vedic Aryans. The Massagetæ occupied precisely that position to which the legends of Mount Meru and its rivers, (amongst the rivers are the Jaxartes and the Oxus may be clearly traced) point as the cradle of the Aryan race, and the early mention of the Sacæ (Sakyas) and Bactrians (Yavanas) as the principal foreign nations, confirms the supposition that the Aryan race travelled Southwards from the high lands of Central Asia, before entering the Punjab. The Aryans of the Vedic period were but barbarians or nomades. We have mention in their hymns of cities of commerce, merchants, sailors, of weapons of wood and iron of chariots, of heralds, travellers and inns for their accommodation and even of the vices of a primitive civilization.

(2936) VELLAI PUNA PINU, the Tamil name of a tree, which is the white peon pinu: it can be procured on all parts of the coast of Malabar. It grows to seventy and eighty feet long, and to three feet in diameter; the natives use it for the masts and yards of dories and country vessels. It is more like the American white pine, and the upright yellow wood at the Cape of Good Hope. (Antinaguatis), than any wood seen.—*Edye, M. and C.*

(2937) VELLA VENGAI, the Tamil name of a tree, the wood of which is of a light colour, and very tough and strong, and is used by the natives for the frames of vessels, or where strength is required; it grows to about eighteen inches in diameter, and twenty feet long, and the small branches make good boat crooks.—*Edye, M. & C.*

## VICHITRA VIRYA.

(2938) VELATTI, the Tamil name of a wood which resembles the English pear tree. It grows to about twelve inches in diameter, and fifteen feet high: it would answer well for carve-work, from the fineness of its grain.—*Edye, M. & C.*

(2939) VELLIELLUS, a tree of little use; it is used by the natives for house work; its growth is small, and it is rather scarce.—*Edye, M. & C.*

(2940) VELLE-ELow, the Malayala name of a tree that grows to about sixteen feet high, and eight inches in diameter. It is used by the carpenters for the frames and knees of country vessels. It produces a white seed which the natives use medicinally.—*Edye, M. & C.*

(2941) VELLIE PUNA, known in Malabar as the white or Cat-Puna. It grows to about eighteen inches in diameter, and eighteen feet high and is used by the native carpenters for the frames of vessels. It grows curved; and is not durable. It is not found in any quantity in the forests.—*Edye, M. & C.*

(2942) VEMBAH, the Tamil name of a tree, which grows in Travancore, it is close grained and of a yellow tinge, and grows to about twenty-feet long, and fifteen inches in diameter; it is used for native purposes. The bark of this tree is stripped and used by the natives in cases of eruptions on the skin; and also to purify the blood after fevers, for which it is considered most valuable.—*Edye M. & C.*

(2943) VENARAH, the Malayala name of a jungle-tree which grows to about twenty-four feet in height, and eighteen inches in diameter. It is used in building native vessels and for other native purposes.—*Edye M. & C.*

(2944) VENDIDAD SADE, a religious book of the Parsees. See ZOROASTER.

(2945) VENGENDAH, the Tamil and Malayala name of a tree which the natives use for catamarans and rafts for heavy timber; it is remarkably soft and spongy, and not of much use or durability.—*Edye, M. and C.*

(2946) VETTE MARAM, the Malayala name of a tree that grows to about twelve feet high, and eight inches in diameter. Its wood is much admired on account of its handsome dark streaks of black and brown, with white and yellow ground. It is very much like ebony in grain, and also in leaf. It produces a flower which is considered sacred: and is used for decorating the women on days of ceremony at the pagodas.—*Edye. M. and C.*

(2947) VICHITRA VIRYA married Amba and Ambahka, daughters of the King of Kasi, who had issue after his death by his half brother Krishna dwaipa yana or Vyasa, Dhirita rashtra and Pandu, whose wives bore the five Pandavas viz.

- 1 Yudishtira.
- 2 Arjuna, father of Parikshita,
- 3 Bhima.

## VIRAM PILA OR JACK-WOOD.

- 4 Nakul
  - and
  - 5 Sahadeva,
- } who founded the Magadha line.—*Prinsep by Thomas.*

(2948) VIJAYANAGAR. The family genealogy deduces a descent in the direct line from Pandu of the lunar dynasty, and imperfectly follows the Pauranic lists to Chandrabija, the last of the Magadha Rajas. The first in authentic history is Nanda, A.D. 1034, who founded Nandapoor and Warangal. Between A.D. 1524 and 1565, Rama Rajah was killed in an invasion of Nizam Shah Bhairi and Imad-ool-Mulk. In the time of Tepu, Sultan Khan took the country in the name of Tepu, and in 1829, the dynasty became extinct with Vera Venkatapati Rama.—*Thomas' Prinsep.*

(2949) VIKRAMADITYA, B. C. 56. Samvate era.

(2950) VIKRAMADITYA ERA. The era of Vikramaditya, is in general use throughout Telingana and Hindustan, and is called Samvat or vulgarly Sambut. The prince from whom it was named was of the Tuar dynasty and is supposed to have reigned at Ujjain (Ujjayini) 135 years before Salivahana, the rival founder of the Saka era, South of the Nerbudda. The Samvat era commenced when 3044 years of the Kali Yug had expired, i.e., 56 years B.C. It is known, though less used throughout Bengal, Tirhut and Nipal and is nearly unknown in the Peninsula.—*Thomas' Prinsep.*

(2951) VIKRAMADITYA THE GREAT, flourished in 56 B. C. he was a munificent patron of art and letters.

All the most readable Sanscrit Hindu works, the drama, the lyric, the sentimental and philosophical Kavyas, as Nalas, and the Bhagavad Gita, the Romantic histories and historical romances, the fables, Hitopadesa, Vetala Panchavinsati, and so forth, and most of the works on science, belong to the first ten centuries of the Christian era.

(2952) VIRAM PILA OR JACK-WOOD. This is the Tamil and Malayala name of a tree which is well known to Natives and Europeans. It grows in the native cultivated grounds, and pays a duty to the Government. This tree is of the greatest value to the natives, in consequence of its fruit, which forms part of their food. In Ceylon it supports the pepper-vine. In many places it is found two feet and a half in diameter, and from thirty to thirty-five feet high. In Canara this wood was preferred by Tipu Sultan for the Grab vessels built at Honore, the naval depot. In Ceylon, at Point de Galle, it is used by the furniture-makers for chairs, couches, &c., for which purpose it answers well, and, if polished with care, its brilliant colour is superior to that of Mahogany. When worked and cut down it is yellow, but turns dark and improves by age.—*Edye. M. & C.*

## VOLCANOES OF INDIA.

(2053) VISHNU PURANA. The fourth book of this work contains all that the Hindoos possess of their ancient history. It is a tolerably comprehensive list of dynasties and individuals: it is a barren record of events. It can scarcely be doubted however but that much of it is a genuine chronicle of persons, if not of occurrences. The Vishnu Purana has kept very clear of particulars from which an approximation to its date may be conjectured. No place is described of which the sacredness has any known limit nor any work cited of probable recent composition. The Vedas, the Puranas, and other works forming the body of Sanscrit literature are all named; and so is the Mahabharata to which therefore it is subsequent. Both Bauddhas and Jains are adverted to. It was therefore, written before the former had disappeared; but they existed in some parts of India as late as the twelfth century at least, and it is probable that the Purana was compiled before that period. That it is discredited by palpable absurdities, in regard to the longevity of the princes of the earlier dynasties, must be granted, and the particulars preserved of some of them are trivial and fabulous. Still there is an inartificial simplicity and consistency in the succession of persons, and it is not essential to its credibility or its usefulness that any exact chronological adjustment of its different reigns should be attempted. Deducting however from the larger number of princes a considerable proportion, there is *nothing* to shock probability in supposing that the Hindu dynasties and their ramifications were spread through an interval of about twelve centuries anterior to the war of the Mahabharata and conjecturing that event to have occurred about fourteen centuries before Christianity, the commencement of the regal dynasties of India is thus carried to about 2600 years before that date. After the date of the great war, the Vishnu Purana, in common with those Puranas which contain similar lists, specifies kings and dynasties with greater precision and offers political and Chronological particulars, to which, on the score of probability there is nothing to object.—*Professor Wilson, pages 64, 65, 70 and 71 quoted at page 235 of Thomas' Prinsep Vol. II.*

(2954) VOLCANOES OF INDIA. By Dr. BUIST.

In touching in last year's Report on the subject of volcanoes and volcanic appearances, real or supposed, in India, I was led to the conclusion that there were in all likelihood not a few of these which wanted sufficient proof to satisfy us of their reality; and I instanced two cases as probably belonging to this category—that of the eruption in the Zabayar Islands, described by Captain Barker as seen in 1846, and the luminous appearance off the coast of Arracan, which, in my inability of laying my hands on the account of the matter which I knew had

## VOLCANOES OF INDIA.

been published somewhere, I thought very likely to have been the result of some of those causes of luminosities which are now known to be of such frequent occurrence at sea. On both points I have since seen good reason to change my opinion, and the occasion of making the required correction seems to be a favourable one for the preparation of a short paper on volcanic phenomena in India. My own means of observation have been in this matter very limited—the only volcanic regions I have actually examined are those to the westward of Kurrachee, and on the South Arabian coast, and those of the Red Sea, much of the most important information in existence on the subject lies hid in the Reports of the Meetings of the Beugal Asiatic Society, which have unfortunately not been indexed, the Table of Contents and Index to the Papers affording no light as to what occurs at the meeting. The subject is the more important as it is obvious from the latest editions of the works of Sir C. Lyell and Mrs. Somerville that they have fallen in with only a small portion of what has been published on the volcanic phenomena of India.

The following letters will set the question as to the Zebayer eruption completely at rest:—

“Sir,—With reference to an article which appeared in the *Bombay Times* of 9th ultimo, wherein you suppose ‘I was misled by appearances, in mistaking the smoke issuing from the Hindostan steamer, for smoke issuing from the summit of Saddle Island, one of the Zebayer group,’ I beg to forward the accompanying statement from Captain Lovell of the P. and O. Steamer Oriental, (but at that time in command of the Hindostan,) by which you will perceive it to be impossible I could have made such a mistake; and it will also account for Captain Lovell not noticing the smoke issuing from the island, inasmuch as we must have been in a line with the island from the Hindostan at the time she saw us. I am perfectly convinced there was neither mistake nor delusion. The smoke was first pointed out to me by Assistant Surgeon Nicolson, and seen by all on board the Victoria, not at one moment, but at different periods; and at the time it was first seen, the Hindostan was to N. N. W. of the Quoin Rock, the northernmost of the Zebayer group, and distant from the Victoria at least 16 or 18 miles, in a contrary direction. I should not have been justified in approaching nearer to the island as we were “dead to windward of it,” and it was blowing violently. The vessel's speed being reduced from 7 to  $4\frac{1}{2}$  knots per hour; force of the wind 9, height of waves 5. J. W. BARKER,

Commander, Indian Navy.

P. S.—With regard to no notice having been taken of the explosion by the native craft, you must bear in mind that the island is quite out of their track, inasmuch as they always navigate

## VOLCANOES OF INDIA.

the inner channel ; and even supposing they had seen it they would probably have viewed it with the same apathetic indifference our Arab pilot did—merely exclaiming, Verily, it is the work of evil spirits..

14th August 1846. 8 A. M.—Passed Jibbel Teer all sail set with a light breeze from Nd.

9. A heavy black cloud, rising rapidly from the S. W., which in half an hour formed into about a dozen large water spouts.

10. Saw the Quoin Rock.

10. 30. The squall burst upon us with heavy rain and blowing furiously, with much lightning and a continuous roll of thunder, which had a very peculiar sound, as if close upon the water. Hauled out S. by W. Ship steering previously S. S. E. At 11.30 the rain abated a little : saw the Zebayer islands bearing easterly, distant about 7 miles—and a steamer between us and the islands, distant from us about 4 miles. The weather continued thick and squally, with much lightning, till we got as far as Mocha.

The Barometer was very slightly affected by it.

Henry P. LOVELL,

*Acting Commander Steamer Hindostan.*

I was on board the steam vessel Victoria at the time that Commander Barker alludes to, and noted down at the time, all the circumstances relating to this sudden outbreak of Saddle Island, and I give you the substance of my notes, from which you will at once see that your explanation does not tally with the facts of the case :—‘ 14th August 1846, off Sobayer Islands, lat. 15° 7' long. 42° 12,' on the voyage to Suez. The whole forenoon has been calm and excessively sultry. Skies overcast ; particularly dark and threatening towards the N. W. Thermometer 95°. Sighted the Peninsular and Oriental Steamer bound for Aden : she passed about four miles to the west of us as we were closing in with the group of Islands. Soon after she passed a violent squall from the N. W. burst upon us.

It was accompanied by a drenching shower of rain, heavy peals of thunder, and vivid flashes of lightning. Ship going about eight knots during the forenoon—reduced to three knots when the squall came on : temperature brought down to 80 degrees. Passed along the western side of the Sobayer group of islands. When opposite to Saddle Island (one of the Sobayer group,) and only about three miles distant from it, observed a column of smoke issuing from the summit of one of its cones. The squall was then at its height. The column gradually increased in size, while at the same time, distinct jets of smoke issued, as if from numerous small apertures round the outer margin of the cone. Before the squall burst, the summit of the island was perfectly clear. After passing the island, and while it continued in sight, we observed the smoke. This sudden change affected almost

## VOLCANOES OF INDIA.

every one on board, less or more, with a feeling of languor and depression of spirits : several individuals, and I myself was one of them, complained of great uneasiness and sickness at stomach.’ This is the substance of my note, and it clearly shows that your mode of explaining away is without any foundation in fact, for both steamers passed along the same side of the Zebayers, and when we first observed the smoke issuing from Saddle Island, which was then due east of us, the Bengal steamer was well down nearly due south of us, while the wind blew very fresh from the N. West.

Suez, 6th November, 1850,” J. G. N.”

This furnishes one more illustration to the hundreds we possess of the intimate connection betwixt earthquake, volcanic, and meteorological phenomena so well adverted to by Captain Baird Smith. During the Cleopatra’s hurricane of the 19th April 1847, and again at the period of the land squall on the 6th April, 1848, the magnetic instruments at Bombay continued in a state of great disturbance for upwards of two days.

The following note of the loss of polarity by the needle during a whirlwind is given in a letter in the Bombay Times, May 30, 1846 :—

“ There is a class of magnetic local perturbations apparently confined to these seas, one of which was experienced by the Queen on her late voyage from Aden, which we do not remember to have seen noticed by magneticians. When about three hundred miles from Bombay the people on board the steamer observed the atmosphere get suddenly clouded all around with that strange lurid appearance which indicates the approach of a burst of rain or hurricane. By and bye appeared overhead those strange and turbulent vapours commonly attendant on a whirlwind or waterspout,—and a light whirlwind accordingly made its appearance. At this time the magnetic virtue of the compass appeared to vanish : the needle lost its polarity and traversed equally in all directions. A state of matters so surprising was of short endurance : the sky cleared without a tempest, and all went well again. It is we think about two years since an accident of this sort was met in with by the H. C. schooner Mahi on her way from the Persian Gulf. She was surrounded by beautiful groups of whirlwinds and waterspouts ranging about her in all directions, when suddenly the needle lost its polarity and continued for some time useless for the purpose of steering. We are unable to lay our hands on the account of the circumstance published at the time, but remember perfectly its occurrence. To these we may add many others. Dr. Bradley has clearly established the fact that our lesser whirlwinds at all events are either due to direct electrical agency, or, are characterised by the most striking electrical exhibitions.

The occasion of making these corrections seems a most suitable one for throwing into

## VOLCANOES OF INDIA.

connected form the information that lies scattered up and down in a multitude of different quarters in reference to volcanoes in India meaning by this general term within the region betwixt Burmah and the Red Sea, between the parallels of 10 and 30. These consist of the group betwixt Barren Island and Chittagong, which terminate the vast Molucca band — of the band stretching westward, consisting mostly of hot springs and mud volcanoes betwixt the Nerbudda and the sea coast of Suez — a range of above 500 miles in length, and the magnificent region extending from Aden to near Ankobar betwixt 10° and 12° 45' N. lat. and 40° and 45° E long.—a base of full 400 miles, and extending to Gibbel Teir, 15 30 N., a distance of 350 miles, with probably little diminution, in its breadth.

### *Volcanoes in the Bay of Bengal.*

“One of the most terrible active group of volcanoes in the world,” says Mrs. Somerville, “begins with the Banda group of islands, and extends through the Sunda group of Timor, Sumbawa, Bali, Java, and Sumatra, separated only by narrow channels, and altogether forming a gently curved line 2000 miles along; but as the volcanic zone is continued through Barren Island and Narcandam in the Bay of Bengal, (lat. 12° 15,) and northward along the entire coast of Arracan, the entire length of the volcanic range is a great deal more.” [Physical Geography, vol. I., p. 257, Ed. 1851.] The band is not as will presently be seen, limited to Arracan, but extends northward to Chittagong, lat 22° or 600 miles beyond Barren Island. The first description we possess of the volcano in question is that of Lieutenant Colebrook, [Asiatic Researches, vol. III p. 396,] who visited it in 1787, when it was in a state of violent activity; he does not seem to have landed on it, and he quotes entire the account of it given by Captain Blair in his survey of the Andaman Islands. The cone which springs from near the level of the sea, rises at an average of 32° 17, to 1800 feet nearly. [Later authorities make it 500 feet, and this is probably its true altitude, Captain Blair gives no separate representation of it on his chart; he merely sets it down as a volcano,] Mr. Lyell gives the following account of it—he quotes Von Buch as his authority, a work I have not been able to consult:—“Barren Island, in the Bay of Bengal, is proposed as an illustration of the same phenomena” (that of ancient craters, of elevation, as contrasted with modern craters of eruption) “and here, it is said, we have the advantage of being able to contrast the ancient crater of elevation with the cone and crater of eruption in its centre. When seen from the ocean this island presents on almost all sides a surface of bare rocks, which rise up with a moderate declivity towards the interior: but at one point there is a narrow cleft, by which we can penetrate into the centre and there discover that

## VOLCANOES OF INDIA.

it is occupied by a great circular basin, filled by the waters of the sea, bounded all round by steep rocks, in the midst of which rises a volcanic cone, very frequently a source of eruption. The summit of this cone is 1690 French feet in height, corresponding to that of the circular border which encircles the basin so that it can only be seen from the sea through the ravines.” [Elements, 1830, Vol. I. page 390. This seems to be taken from Captain Blair’s estimate of 1800, since upset, as already stated, by Captain Miller, Dr. Adam, and others.] Barren Island was visited by Dr. John Adam in 1831. The water close in shore was then hot and steamy, while steam and smoke issued from the crater, but no lava or flame. He estimates the diameter of the base at about 800 or 1000 yards, and the orifice of the crater, which occupies the entire summit of the cone, at about 30. [Bengal Asiatic Transactions, 1832, Vol. I.] The latest description that has been published of Barren Island is that of Captain Miller, who visited it in 1834. [Calcutta Journal of Nat. Hist., 1843, Vol. III.] His account of it is the same in its general features as that of Lyell, but he estimates the altitude of the cone at no higher than 500 feet; and considering the limited distance to which it is visible at sea, this seems to be more correct than other estimates. He sets down the slope of the cone at 45, which would give an altitude of above 1,000 feet, were Dr. Adam correct as to the diameter of the base. He states that it could only be ascended by climbing, and it is probable that Captain Blair’s assumption of 32.17, which was determined by measurement, may be near the truth. The volcano, like the others along the bay, is chiefly active during the S. W. monsoon.

Next to Barren Island is the volcanic island of Narcandam, lat. 13° 22. The cone, is about 800 feet high, no soundings are to be had within half a mile of the shore [Report of Calcutta Coal Committee, 1839.] Crossing over to the other side of the bay where perfect tranquility seems for nearly a century to have reigned, we find a period when the Coromandel Coast was as much moved by volcanic agency as that of Arracan itself.

The earliest account we possess of any actual eruption in the Bay of Bengal is that contained in the 1st vol. of the Annual Register, 1776, reprinted in the Bengal Asiatic Transactions of 1847. [Bengal Asiatic Transactions 1847, vol. xvi p. 499 Reports and Asiatic Researches, vol. I p. 175.] It was written by an officer on board a French East Indiaman, and addressed to his friend at the Hague: there seems no reason to question its perfect accuracy. In July 1757, fires were seen from Pondicherry to break out on the surface of the sea three or four leagues from shore. These blazed out with the greatest fury, throwing up pumice stone

## VOLCANOES OF INDIA.

and combustible matter. This was accompanied by a noise like thunder, or the discharge of heavy ordnance. An island a league in length and about the same in breadth, with a cone and crater in the centre, then appeared. A vast quantity of dead fish were afterwards seen floating on the surface of the water, destroyed by the eruption. The sea was some days afterwards so covered with pumice stone that vessels found it difficult to make their way through it, while they ran the risk of being burnt from the showers of hot ashes with which the air was darkened. The island seems speedily to have subsided again as we hear no further mention made of it. A shoal, called the Goris Bank, was seen by H. M. S. "Melville" in a line joining Pondicherry and Chittagong, and a shoal is noted on an old chart as having been met in with by an American ship in the line betwixt Pondicherry and Chedooba: both these have since then disappeared. Mr. Piddington remarks that the middle of last century was the great epoch of earthquakes all over the world. [Mr. Piddington on the subject of eruptions.—Bengal, Asiatic Transactions.]

In 1750 Chili was visited by an earthquake, by which the Town of Concepcion was destroyed: the sea rolled over it, and the entire port, from thenceforth became useless. The whole shore seems to have sustained an upheaval of about 24 feet; and shells similar to those found in the adjoining seas are now abundant on mountains above 1000 feet high, [Lyell's Elements, vol I p. 440 edition 1850, p. 431, gives it 1848 English feet.] On the 15th September, 1751, the capital of St. Domingo was destroyed by an earthquake, and part of the coast, 40 leagues in length, sunk down, and has ever since formed a bay of the sea. The Lisbon earthquake, one of the most fearful on record, occurred in November, 1755, and in 1757 the Azores were struck with an earthquake, during which eighteen small islands arose, about 200 yards from the shore: these corresponded very closely with the Pondicherry explosion. The following extract is from Dr. Thomson's paper on the Geology of Bombay (Mad. Lit. Trans.) It bears directly on the subject, and carries us three centuries further back: I have not considered the description specific enough for the text, but see no reason to doubt the authenticity of the fact:—"The island of Vaypi, on the north side of Cochin, rose from out the sea in the year 1341: the date of its appearance is determined by its having given rise to a new era amongst the Hindoos, called Puduvepa, or the new introduction. Contemporaneously with the appearance of Vaypi the waters, which during the rainy season were discharged from the Ghaut, broke through the banks of the channel which usually confined them, overwhelmed a village, and formed a lake and a harbour so spacious that light ships could anchor where dry land for-

## VOLCANOES OF INDIA.

merly prevailed."—Bartolome's Voyage to the East Indies Rome 1796; Translation 1800.] The volcanic region in the Bay of Bengal seems about the year 1750 to have been in a state of general activity. Off the coast of Arracan, lies an island called Chedooba situated in lat 18°50' N. and long, 90°40,' fifteen miles in length and seventeen in breadth, or of about 200 square miles in area. Its general appearance is that of a fertile, well wooded island, of moderate height and irregular outline. A band of level land, covered with fragments of coral shells, and gravel, and but a little way elevated above the sea surrounds it: three distinct terraces are visible, the result of so many separate upheavals. [Captain B. Smith, in his admirable paper on Indian earthquakes, published in 1842.] Bl. As Trans, Vol. XII, gives an account from the "Gentleman's Magazine" of a violent earthquake which occurred at Calcutta in 1737. Twenty thousand vessels of various sizes are said to have been destroyed by the inundation which accompanied it, and 30,000 lives are said to have been lost on the occasion. No volcanic phenomena, strictly so called, seem to have attended it. It took place during a furious hurricane. The earliest Indian earthquake of which particulars are given is that which accompanied the hurricane of 26th May 1618, by which 2000 lives and 60 vessels are said to have been lost at Bombay [See Madras Lit Trans 1837 already quoted from Gower's Portuguese India tome III.] There are four large volcanoes in Chedooba, detached mounds rather than cones, varying from 100 to 1000 feet above the level of the sea. They are composed of stiff grey clay, with large quantities of singular fragments of stone: their sides are much cut up with rain; their summits, which are from 50 to 240 yards in diameter, are quite bare.

(Abridged from Capt. Halsted's Report on the Island of Chedooba Bl As. Trans. 1841, vol. X. p. 434. Capt. Halsted gives maps of the islands of Chedooba and Regwan, adjoining to it. The latter is copied into Johnstone's Physical Atlas, map 3.) On the summits of these are numerous well formed cones, from a few inches to four feet in height, and about the same in diameter. On the outside they are hard, within they are filled up with a thick, uniform, well-mixed mud, which every now and then runs out at the side or over the edge of the crater, bubbles of gas rising at intervals of three or four minutes; there is no appearance of eruptions of lava scoria, or vestige of the agency of actual fire: some of the volcanoes throw out hot sea water in place of mud: they are most active during the rains, and then occasionally emit flame and stones, as well as mud, throwing these to a considerable height: the stones are obviously torn from the beds through which the water passes; portions of copper occasionally adhered to them. Petroleum wells abound here, as they do all round the

neighbourhood. Capt. Halsted visited Chedooba in 1841 and his survey in the "Childers" extended above 100 miles along the coast. The shore here is marked by three well-defined terraces, or raised beaches, covered with coral and shells, and manifestly the result of three distinct upheavals, with considerable intervals—of just a century, the natives believe, betwixt them. The uppermost of these is less conspicuous and distinct than the two lower, but on the western coast a remarkable column of rock stands out on the beach, about 40 feet high, with oyster shells still attaching to it, showing the second line of beach, just thirteen feet above the first. The last of these was said by an old man of 106, who remembered it when he was a lad of 16, to have occurred about the year 1750. [Note. Mrs. Somerville. (Physical Geography, vol. I. p. 254,) speaks of these as the result of gradual upheavals going on within the last hundred years: it appears to have been the effect of sudden and instantaneous elevation, occurring just a century ago. There is no evidence of any subsequent change of level having occurred within this period along the shores of the Bay of Bengal] Mr. Piddington suggests that it is not unlikely that it may have occurred simultaneously with the eruption at Pondicherry in 1757—natives being proverbially inaccurate as to dates—during the occurrence of violent earthquakes, when the sea washed several times over the lower part of the island, and then permanently retired as the land, emerged. Captain B. Smith thinks it likely to have occurred during the Chittagong earthquake of 1762. Immense quantities of fish were found on the recovered land, and the feasting which occurred on these is still a favourite tradition in the islands: no rent occurred in the earth, and no lives were lost, or mischief occasioned: for more than half a century much of the soil remained salt. The elevation has been greatest towards the centre of the line examined, where it is twenty-two feet; at the termination it is thirteen, and at Foul island mine, Regwan, lat.  $18^{\circ} 37' 49''$  just to the north of Chedooba, is marked by three distinct risings, [Note of Lieut. McVulloth, R. N. Map of Ragwan. Bl. As. Trans; Johnstone's Physical Atlas.] each about eight feet: the outer portion of the island was said to have been raised about 1760—most likely as Mr. Piddington supposes, 1757. The original island contains two terraces, about nine feet high—the outer margin is as yet barren; it consists generally of corals, shells, and gravel; the rest is a level plain of rice fields. In the adjoining island of Ramree, or Rumbree, off Kyouk Phyoo, there are some beautiful mud volcanoes, the cones of which are almost all covered with luxuriant casuarina trees—the only places where they are found in the neighbourhood. The craters and expelled matter possess the same

[Note. Dr. Spry. Bl. As. Trans. 1851, vol. x. p. 1845.] This was first described by Lieut. Foley, in vol. 4th of the Asiatic Journal: the cones are said by him to vary from five to 1500 feet, one peak, called Teaka, reaching the altitude of 3000. Vapour and flame were seen to issue from one of the peaks during the earthquake of 26th August 1833.

There are various hot springs at Chittagong subject to periodical eruptions, and which constantly emit gas and flame.

There is a small volcano near Kyouk Phyoo in a constant state of activity, and which frequently emits smoke and flame. Cottages at the distance of four miles from it were on the occasion of the eruption of 1842 brightly illuminated, yet so little was the heat that the specimens from the crater were no where melted.

Within little more than ten years of the elevation of the island off Arracan a catastrophe, precisely the opposite of that from which Chedooba suffered, overtook Chittagong. During the great earthquake of April 1672, sixty square miles of the lowlands along shore were permanently submerged: Ces-lung-toom, one of the Mug Mountains, entirely disappeared, and another sunk so low that its summit only remained visible. [Phil. Transactions, 1763, given entire in Capt. Smith's paper on earthquakes, Bl. As. Trans. vol. xii. p. 1047, quoted in Report of Coal Committee, republished in the India Review, 1839. p. 71. I have introduced the passage, into the text nearly unaltered.]

Four hills are described as having been violently rent asunder, leaving open chasms, varying from thirty to sixty feet in width. Other mountains and hills were variously disturbed; some were partially thrown down so as partly to disturb the courses of rivers. One eminence became degraded by little and little till it returned to the level of the plain. In the plain, the earth opened in several places throwing up water and mud of a sulphureous smell. At Barcharra 200 lives were lost on a track of ground that sunk suddenly. It is said that at Arracan the effects of the earthquake of 1772 were not less fatal to human life and property than those of the Lisbon one in 1755; while at Dacca the waters rose so suddenly as to throw all the boats on shore, on its retirement sweeping multitudes of human beings away. From the notices of islands now no longer to be found on the western shore of the Bay of Bengal, in the accounts of Arab navigators, there can be no doubt whatever that numbers of these have been from time to time submerged. [Mr. Torrens, Bengal Asiatic Journal Reports, Feb. 1845. p. XXVI; Ibid p. XXII.]

About an hour after sunrise on the 26th July 1843, the inhabitants of Chedooba and Flat Island heard a great noise, and saw fire rising out of the sea; an earthquake had been felt just before—this continued for four days, when on the

29th a small island seemed to arise above the surface of the waters: It continued visible for about a month, but it was now the monsoon, and the weather was too boisterous to permit its being approached. In October, on the return of the fine season, search was made for it, but no trace of it could be found. A careful survey of the spot was afterwards instituted by order of Government, but no indication of commotion, and no change in the aspect of the shore, or bottom of the sea was discoverable. [Ibid, Dec. 1843, Vol. XII, Ibid, Vol. II. p. 1117.]

On the 2nd January 1845, between the hours of six and seven p. m., about an hour after sunset, the people of Kyouk Phyoo, on the coast of Arracan, were astonished to see the eastern horizon to seaward become brightly illuminated: it continued flickering, like the reflection of distant flame from a ship on fire, for about half an hour, when suddenly immense volumes of flame were seen to burst as if from the depths of the ocean, presenting a most sublime and awful spectacle to beholders. It was accompanied by a low continuous rumbling sound, which seemed to ascend from the bowels of the earth, and was re-echoed from the hills around. The duration of the exhibition is not mentioned, though it was seen by many witnesses: it seems to have been very transient. A vessel was sent out to sea immediately, under the impression of its being a conflagration, but saw nothing. Government, on being applied to by the Asiatic Society, instituted a careful survey of the coast, but no change in the depth of the soundings or character of the bottom could be discovered. There can at the same time, remain no reasonable doubt that the exhibition was volcanic—probably a sudden emission of gas through an aperture or crevice not detected by the sounding line. [Three accounts of this most singular occurrence are given with minuteness in the Reports of Proceedings of the Bengal Asiatic Society for February 1845, p. 24-28, not indexed. The best account is that of Lieut. Hawkins.]

The extreme frequency of earthquakes in Assam would lead to the inference that it was the theatre of lively volcanic action. No fewer than twelve of these occurred betwixt May 1834 and May 1835. "About twenty years ago," says Dr. McCosh, writing in 1837—that is about 1817, "the natives inhabiting a small knoll near the hill of Goalpara were so terrified by the unusual shaking of their little hill, that they fled from it for safety, and ran to a distance: on their return their houses and hill had disappeared, and a large pool of water, thirty or forty feet deep, occupied its place." [Topography of Assam, by Dr. McCosh. Calcutta 1837.]

The region of recent direct volcanic action seems, so far as we at present know, to terminate with the extremity of the Delta of the Ganges. [Col. Conesley, Bl. As. Trans. Vol. XVII. p. 1.]

A few hot springs are all we have to indicate the agency of a subterranean fire for nearly 1000 miles across the Peninsula. There are hot springs in the Damoodah valley, 23° 10' N. in Gangetic India, in Kunawar, in the lower Himalayas, and near Lohunkund, on the Sutlej. The most notable of these is that at Sargunga, near Chota Nagpore, in Central India, where the temperature of the water is 184°: it smells strongly, and seems to be a Harrowgate. [The following is from Capt. Baird Smith's memoir on Indian Earthquakes. I have not met in with the work of Dr Falconer referred to as expected in 1843, nor, indeed with any more recent account of the field of fire than about to be given: but from the frequency of our visits at Cashmere since 1846, I should suppose it must have been frequently since described.]

"Whether recent travellers who have explored the valley of Cashmere have collected any further evidence as to the former condition of the province, I am unfortunately unable to say, as I have not yet been able to consult their works. That indications of active volcanic action are numerous and remarkable, I learn from Dr. Falconer, the latest of the Cashmerian travellers. He informs me that a singular 'field of fire' exists in the valley, of considerable dimensions, and through crevices in which flames continually issue, the outlines of this volcanic tract are distinctly defined and the action appears to be strictly local, the soil is completely burnt, and in some spots I believe, vitrified. The igneous action has continued now for upwards of two centuries, as the existence of this remarkable spot is certified by Abul Fazil, the learned minister of the Emperor Akber. [Second Report on Geology of Hyderabad.] Dr Vosey describes a hot saline spring near Hyderabad in the Deccan. [For the above particulars, I am indebted to Dr Falconer. They were given verbally, and are quoted from memory, so that they are rather indefinite; but as Dr Falconer's own account of the phenomenon may be expected ere long, it will be in my power to correct and enlarge the above notice.] Mr. Moorcroft in his travels, (Vol. ii. p. 277) mentions a hill within three days' journey of the city of Cashmere, from which loud explosions are heard at intervals, accompanied by the escape of gaseous matter, with force sufficient to tear off the doors and windows of buildings situated upon it. There was nothing on the hill resembling a crater, but the inhabitants on the spot asserted a distinct recollection of the explosions."—Bl. As. Trans. vol. xii, part II for 1843. p. 1046.] In the Concan there are no fewer than twelve hot springs betwixt Dasgaum and South Rajpore, and they are supposed to follow the line of the great Ghaut chain southward to Ceylon: the majority occur near the great lines of dislocation. There are two hot springs in Candeish

and several in Kattiawar, and lower Scinde, as we shall presently see, abounds with them.]

Lake Loonar, in the Sihal Hills, is the only instance of a volcanic outburst observable in this immense Plutonic region. [Malcolmson, London Geological Transactions 1839. It was first described by Lieut Alexander, in the Madras Literary Transactions, subsequently by Mr. Orlebar in the Bombay Geographical Transactions.] It is a nearly circular or oval depression in a country composed entirely of tabular and nodular basalt: it is 500 feet in depth and three or four miles in circumference. In the bottom of the hollow is a lake five feet deep, the waters of which are impregnated with muriate and sulphate of soda, and sulphate of lime; subcarbonate of soda prevails in the neighbourhood. In 1851 it was examined by Dr. Bradley, who met with abundance of scorix in the neighbourhood, and was able to trace a vast stream of lava to the east and westward. The great intervals betwixt the points of volcanic activity in this part of India, even when connected by hot springs, prevents them from being associated as groups anywhere betwixt Arracan and Cutch.

On the 27th May, 1846, a hill on the Nerbudda, called Dumoh Phar, or smoking mountain, about 500 feet high above the plain, gave out alarming moans, to the terror of the neighbourhood, and then an enormous outburst in it occurred. The appearance this presented when examined shortly afterwards by Col. Skene and Lieut. Briggs was such as might have been produced by the explosion of a mine, making a rent in the hill from top to bottom about thirty feet across, and six feet deep. Great trees were upset by it, and the rocks rent twenty to thirty feet in pieces, as if blasted by gunpowder, and thrown to the opposite sides of the fissure. The appearance presented in no way resembled that of a land slip—the bursting force had obviously been from the interior. It was not stated that any erupted matter had been thrown out; there was no appearance of any volcanic vent in the neighbourhood, and no tradition of volcanoes ever having existed. [Bl. As. Trans. vol. xvi.]

In the end of October 1849, something like an ebullition of pestilential gas, the discharge probably of a submarine volcano, occurred off Porebunder in Kattiawar, and was manifest for thirty or forty miles out at sea: the fish were poisoned by it, and for days lay floating in myriads on the surface of the water. [See Report of 1850. B. G. S.] An incident similar to this had occurred at Berampore, in May 1810: the water in a large tank, usually pure, and which for a period of thirty four years had never exhibited anything extraordinary, suddenly became of a dark green colour, and an immense quantity of fish, many of them weighing from eight to fourteen pounds, floated dead on the surface, and were afterwards removed in cart loads, and made

use of as manure, the people ascribed it to an earthquake, [Asiatic Annual Register, vol. xii p 465] which then visited Calcutta.

There is no record of the Cutch volcanoes having ever been in a state of permanent activity, and they seem rather to have played the part of spiracles to the gases of earthquakes, when “the earth, seemed with a kind of colic, pinched and vexed,” with fits of vomiting of lava or of flame. On the border of the chain of mountains, and eighteen miles from Lukput, the most westerly town in Cutch, is a hill believed by the Hindoos at one time to have been a volcano. It has long ceased to emit flame or smoke, but is still an object of worship amongst the Hindoos. [McMurdo's Account of the Province of Cutch, Bombay Lit. Trans. vol. ii., p 210, 4-to edition.] It does not appear to exhibit any vestige of lava, scorix, or ashes; a bituminous earth, with a strong disagreeable odour, is dug out of the side of it, and used as incense in the worship of Assappoora: it is found in small pieces imbedded in the common soil, from which it is separated without difficulty.

On the occurrence of the great earthquake shock of June, 1819, vast clouds of dust were seen to ascend from almost every hill or range of hills in Goozerat and Cutch; smoke was in many cases visible, and some flame was perceived. [Dr. Thomson, in his account of the Geology of Bombay, published in the Madras Literary Transactions for 1837, after describing the hurricane and earthquake which occurred all along the coast on the 15th and 16th May, (the 26th and 27th new style, exactly 200 years to a day before the occurrence of similar events in 1848,) says:—Besides the appearance of a violent commotion in the atmosphere, and a perceptible concussion in the earth, volcanic action seems to have occurred, if we may be allowed to deduce such an inference from the highly embellished representations of the historian, of giants seen in the air throwing great globes of fire at each other, confusion of human voices in the atmosphere, the trampling of horses, and the sound of warlike instruments. It is added that much of this nature occurred in Salsette and other places. (Souza's Portuguese India, tome iii.) “The metaphorical figures,” concludes Dr. Thomson, “expressed in the latter part of the description, are strikingly similar to those employed by Dion Cassius in his account of the eruption which destroyed Herculaneum and Pompei, where we are told, giants were seen, and the sounds of trumpets heard in the vicinity.” There is so little appearance, of any recent volcanic eruption near Bombay that I should be disposed to ascribe the appearance, probably in both cases, to the meteorological phenomena always coincident with earthquakes and volcanic action.] At a place twenty-six miles west from Bhooj, fire was seen in considerable

## VOLCANOES OF INDIA,

volume to burst forth; a blazing ball was projected into the air and fell to the ground, where it was broken into four or five pieces, on which it became extinguished and invisible. No fragments could be discovered, but the vegetation was found scorched where it fell. On being examined next day, the hill was found rent and shattered, as if something within had sunk. Fire to a certain extent, was said to have issued from a bituminous hill from which alum is made, near Mru: the height of the hill was considered to have been reduced, and it was rent and shattered into ravines. Near the town of Sinderee, situated where a branch of the Indus joins the Runn, and which was permanently submerged on the occasion, a number of small cones, six or eight feet in height, burst up from the ground, and continued for many days to emit bubbles of air and mud from their summits. [McMurdo's account of the Earthquakes of Western India, 1819, Bombay Lit Trans, vol III p. 105.] The first and greatest shock occurred about seven p. m. on the 16th June: lesser shocks continued till the 20th, when the volcano called Denodour, about twenty miles N. W. of Bhooj, burst into action, and the movements of the earth immediately stopped. [Capt. Baird Smith on Indian Earthquakes. Bl. As Trans vol xii. June, 1843. The authority on which this statement is made is not stated.] Vestiges of recent outbursts, though of unknown date, appear at the village of Wage-ke Pudda. A high table land of volcanic matter, about two miles square, has been blown out into a flat basin, the sides being broken into fissures, with craters, ravines, and hollows; and the interior, or bed of the basin, interspersed with hillocks and cones of every variety of colour—black, red, yellow, and white, and with patches of cinders similar to the refuse of a furnace, the whole looking as fresh as if the igneous agents were still in operation. The surface of the table land immediately surrounding the blown out space is covered with burnt iron-stone, similar to septaria, divided into irregular cells. On other parts of the table land, craters of some fifteen or twenty feet in depth have been blown out: they are composed of the materials just described, and are covered with patches of sulphur. [Grants, Geology of Cutch. London Geol. Trans. 1838, p 316.]

The rocks around the hot springs of Peer Muggen, ten miles west of Kurrachee, consist of nummulite limestone, in some cases highly crystallised, and where the fossils, according to Captain Viccary, occasionally are extensively altered. Two miles further to the westward, occurs the group of Minora hills, about 800 feet above the sea, and 500 above the plain surrounding. On the eastern side a crater has been blown out,—the ruins are scattered around. It is oval in form, about 150 feet in length, and fifty across.

## VOLCANOES OF INDIA.

The explosion has burst away one of the sides, and blown through the strata adjoining. It seems as if a vast deluge of water had for a short time been discharged from it; there is no tradition in existence regarding it, nor is anything known of the date when it was in action. It has clearly been subject to the great changes which have taken place around, though it is probable it preceded the deposit of the post pliocene clays found at its base, as these bear no appearance of disturbance, and have most likely been deposited by the sea subsequent to the explosion. There are several other craters of lesser size and more imperfect structure round Minora.

Capt. Carless, who gives (1838) by far the best account of this district yet published, speaks of a celebrated hill called Jibel Pubb, twenty miles N W. of the hot springs, of which wonderful stories are related all over the country, but he does not tell us what these stories are.

Capt. Viccary describes the clays as post pliocene. He makes no mention of the crater. I visited it and took careful drawings and measurements of it in March 1850. The highly crystalline states of the rock is conspicuous. I confess I could discover no evidence of any material diminution of its fossils around the springs or near the crater. The rocks, which everywhere around are one mass of shells and zoophytes, the corals being often in the most beautifully perfect state that can be imagined, have been in some places highly crystallised, the organic remains being in part obliterated. The crystals are occasionally arranged in beautiful star-like forms, like many members of the zeolite family.

The rocks at the Lukkee Pass—hot springs appear to be of exactly the same description as those at Peer Muggen—their position in all likelihood due to volcanic influences of comparatively recent existence. The hot springs of Peer Muggen attain a temperature of from 100 to 160, and yield a very copious discharge. The water is perfectly pure, and fertilises the soil around. The hot spring takes its name from Peer Muggen a Mahomedan Saint, whose shrine is close by. The coincidence of the sound with the designation given to the long snouted crocodile (muggur) has led to the inference that it was Peer Muggur, the Crocodile Saint. The crocodiles in the tank are of the kind called Gavial: they are precisely similar to those of the Nile and Ganges.] One of the tanks contains nearly 200 crocodiles; there is a spring at no great distance which affords large deposits of sea salt.

The next volcanic group to be met with in this direction is that of Hinglaj, a series of mud volcanoes, very similar in point of form to those of Chedooba, along the sea board of Lus, and now in great activity. Here there is no appearance whatever of there ever having been any eruption of lava. The first of these are called

## VOLCANOES OF INDIA.

the koos of Chundra. They are believed to be of divine origin, and to be possessed of miraculous virtues.

Within two days' sail of the port of Kurrachee, within a hundred yards of the sea, commences the group of mud volcanoes known by the name of the Koops of Rajah Rama Chundra. Three of these were visited by Captain Hart; a fourth was seen by him at a distance, and they are said to be very numerous, and to extend some way along the shore, and far into the interior. About two miles from the wells of Tilook Pooree, three hills, of extremely light-coloured earth, rise abruptly from the plain. [Extracted from the Reports of the Society for May 1850]

The centre hill is conical, slightly flattened, and divided at the top: it is about 400 feet high: its southern and western sides are more precipitous than the others. The second of the group is about half the height of the first; the two are connected by a causeway about fifty yards in length. The third covers a greater area than either; its apex seems destroyed or broken off, otherwise the characteristics of the three closely resemble each other. They are all indented at the base with numerous chasms and fissures, which run into the interior, and their sides are stroked from the summit down as if with sluices of mud or water overflowing from the crater. A basin of liquid mud about thirty yards in diameter occupies the whole summit of the largest of the three. Air bubbles and jets of mud arise from the basin continually—the semi-fluid mass within being constantly disturbed by them. The whole summit of the hill is crusted over with caked mud. The same appearances almost exactly are presented by the craters of the two other hills,—with this difference, that in the case of one of them the mud was said to rise and fall, occasionally overflowing the crater, sometimes sinking in it above 15 feet. A fourth-hill, similar to those just described, was seen at some six miles off, but, 'was not visited. The water and mud all around is salt. The ground at the base of the hills is full of cracks and rents. It is the same volcanic agency, most probably, which gives rise to the hot springs of Peer Muggen, that supply the famous crocodile tank, which feeds or stimulates the mud volcanoes. Abundance of brimstone is found at no great distance, and one eminence some twelve miles off is known by the name of the sulphur mountain." Capt. Robertson describes the whole district, for an area of probably not less than 1600 square miles, from the Hara range westward as covered with mud cones, active or quiescent. He spent a fortnight amongst them in 1849 and could discover no particular day on which they were unusually affected: Captain Hart had been told that on Monday they were more active than they were on other days. "The native tradition regarding them is, that on the

## VOLCANOES OF INDIA.

abduction of the Goddess Seeta by Rawun Sedas-hew, a form of Mahadeo was amongst others occupied in endeavouring to discover the place of her concealment. For twelve years he prosecuted his search unceasingly, but without effect. Worn out with exertion, and enraged at the fruitlessness of the task he had imposed on himself, he dashed his sacred cake on the ground. It broke into eighteen pieces and from every fragment a koop arose. The goddess instantly appeared, and chid his wrath and impieties, assuring him that through his wanderings she had accompanied him in the shape of a fly, which generally sat on his holy cake. In commemoration of his exertions on her behalf, she ordered that every pilgrim should pay his devotions to one of the koos before visiting her temple. The koos are called by the name of her husband Rama Chandra. On nearing the crater, the holy man who precedes the pilgrims continually cries out, Speak oh Rama Chandra!—and to their astonishment, accordingly they find on their arrival the mud at the top in a state of commotion,—evidence to them sufficient that the invocation has been listened to, and the deity is present." [Abridged from Capt. V. Hart's Pilgrimage to Highlaj, Bom. Geo. Trans. 1839, and Reports 1850, p. CVIII. A much more minute and copious account of the mud craters of Highlaj than that given by Capt. Hart is published in the 13th number of the Transactions of the Bom. Br. of the Roy. As. So. for 1850, written by Capt. Robertson of H. M S 8th, it confirms the perfect accuracy of Capt. Hart's account, as far as it goes.]

Turning back on the Indus, we find hot springs in the Lukkee Pass. The range of hills in this neighbourhood is composed of little ridges not exceeding 400 feet above the plain of the Indus, their apices with nearly horizontal strata, their sides abrupt and precipitous and non-nummulitic. The valleys, or intervening spaces between the hills, have been much disturbed. A variegated clay, abounding with gypsum, but containing no fossils, is of common occurrence. A brown, rust-coloured rock is abundantly distributed on the surface in the shape of rounded boulders, the most promising specimens of which are manufactured by the natives at Kotree into iron. Between this and the Indus are numerous low hillocks of aluminiferous clay, used for the manufacture of alum by the Seindees. The hot springs issue from the bottom, from what appears an external crater, of the same general character as those already described near Peer Muggen. There are here several hot springs near each other—they are all salt and sulphureous; the whole valley smells strongly of sulphuretted hydrogen gas, which rises in bubbles from the well, and a scum is constantly gathering on the water, which the natives remove and use as sulphur. Near one of the hot springs is

## VOLCANOES OF INDIA.

an aperture in the rock three inches in diameter, from which, until of late years, a jet of flame used to issue; it was called the peri's fire by the natives, and is believed to have become extinguished on some infidel having bathed in the neighbouring well. [Abridged and slightly altered from Capt. Vicary's account of the Geology of Scinde—*London Geol. Trans.* 1846, Vol. III. p. 34.]

There is a very copious hot and sulphurous spring at Gurrumab (i. e. hot well, spelt Gurruma, Col. Campbell's map), in the Bolan Pass, about 200 miles to the northward. I am not aware of any between this and Lukhee.

The area of the volcanic field of Beila has never been precisely determined: it extends some fifty or sixty miles inland, and at least three times as much along shore.

The band, if band it be, now trends away southerly, from lat.  $22^{\circ}$  to lat.  $12^{\circ}$ , and the next group we meet in with, after a break of above 1000 miles, is that at the mouth and at the lower part of the Red Sea, commencing with Cape Aden, and concluding with Gibbel Teir extending across from the former of these to the Salt Lake Assal, inland from Tadjoura, and so on towards Shoa. [See Dr. Bird's Notes to Capt. Foster's Account of Cape Aden, *Bombay Geographical Trans.* 1840. Referred to in Report of the Society for 1850, Vol ix.] Aden is spoken of by Arab writers as having been in a state of activity within the historic period, and though there scarcely seems evidence sufficient of this to be relied on, and a very strong presumption to the contrary, it has all the appearance of great recency.

The volcano forms the terminal point of Southern Arabia, where the shore, after having inclined gently southward from Ras-el-Hudd.  $21^{\circ}$  N. Lat, at the entrance of the Persian Gulf to  $12^{\circ}$ , stretches almost due west, till it turns up the Red Sea. At no great distance of time it has obviously been an island, and is now connected with the mainland by a low sandy spit four miles long and half a mile across, only a few feet above high water mark: the whole shore indeed, consists of sandy down or salt swamps, only a little above the level, of the sea, and wearing the aspect of recent emergence. The peninsula itself is an irregular oval, five miles in its greater, and three in its lesser diameter. There are numerous little head-lands with sandy bays between all around it. There is at the head of each little bay, and on several points of the shore besides, a level expanse of rolled gravel and sea shells, evidently an old sea margin, brought to light by the same up-heaval that converted the island into a peninsula, and raised the isthmus above the level of the sea. The rocks themselves are all lavas of various descriptions, more or less vesicular, and the volcano affords a vast diversity of igneous minerals. There

## VOLCANOES OF INDIA.

seem to have been from time to time a number of craters in the mountain, one of very considerable magnitude beyond the coal-depot betwixt Ras Morbut and Ras Far Shagan, having been blown outwards, and now remaining as a valley ascending from the sea. The edge of the principal crater is near the centre of the Peninsula. The crater itself occupies the eastern half. It is exceedingly well defined indeed, and at once indicates its origin to the spectator. It is about one and half a mile in diameter, and is nearly circular, affording a circuit of five miles. Of this half a mile has been blown out right down to the level of the sea. The bottom of the crater on which stands the town of Aden and the British Cantonments, is covered with a bed of rolled gravel and sea shells, proving that there has been no trace of eruption since the last general upheaval, which produced the sea beach all along these shores, but which is still believed to have been within the human, perhaps even the historic, period. [See Report of the Society of Civil Engineers May, 1851, copied into "Bombay Times," July 9. Also Miss Fanny Corbeaux's letters. *Athenæum* June 28, and July 5, 1851.] The Shum-Shum range, which forms about half the wall of the crater, reaches an altitude of above 1760 feet. There is a huge crack or slip which cuts above a third off the eastern side of the volcano, and through a portion of this, constituting a narrow gorge or pass, ten feet wide, and twenty or thirty high, the road from Steamer Point enters the crater, and leads to the cantonments. Dr. J. P. Malcolmson supposes this to have been the remains of the latest great eruption of which the effects are chiefly manifest on the table land on the eastern buttress of Sham-Shum: by this the ancient crater was shattered nearly through its centre from the northern to the southern pass breaking into pieces, and separating the whole of the eastern side of the edge of which Seera Island is a fragment,—and in these views I concur. (*Lond. As. Trans.* 1846) On the one side of this which remains the wall of the crater subsides from 1700 to 607 feet, and then breaks away altogether. The rift probably occurred when the side of the crater was blown out and demolished. The walls of the crater as now existing, when seen from the cantonments, present the most magnificent view that can be imagined: one semi-circular precipice, five miles in circuit, ascends some 1776 feet from the plain.

It is in most places perpendicular. The cliff is of a rusty dark brown colour, and full of caverns and recesses, carved almost like the altar screen of a Gothic cathedral. Great streams of lava may be observed from point to point, as if the fiery cataract had been arrested in its progress, and congealed as it flowed from the lesser rents of the principal crater. On many parts of the rock, 500 feet above the level of the sea,—to the

## VOLCANOES OF INDIA.

level of Shum] Shum so far as I know, but the altitude just named is all to which I have examined,—great masses of volcanic ashes are strewed amongst the crevices of the rocks, these generally abounding, as does the surface all around, with sea shells in a state of great decay, to all appearance borne up by the volcano on its last emergence from the deep.

The minerals found at Aden are very numerous. We have almost every variety of lava, compact, earthy, vesicular, amygdaloidal, porphyritic, and obsidian in all its forms, from dull coarse green and bluish-green to beautiful jet black. Pumice is found, but is not plentiful. It is mostly of a dark reddish brown colour, and is heavier and more coarse in its texture than the mineral of commerce, and less suited for the finer purposes of the polisher. Brimstone is sometimes found, but rarely. Rock crystals in veins, nests, crusts, are very plentiful everywhere. On many parts of the volcano chalcedony in various forms abounds; in some cases it appears in thin crusts, in button shaped encrustations or in drops or studs, occasionally covered over with delicate rock crystals. They are of a beautiful bluish white, and take a prominent place in any cabinet. On these are occasionally found small crystals of purple fluor spar, from the size of a mustard seed to that of a sweet pea. Carbonate of lime appears as calcareous spar, frequently filling veins and cavities, as a slightly crystallised veined variety of marble of various tints of brown, exactly like the Gozo marble seen at Malta, and the portions of the Rock of Gibraltar from which ornaments are mostly cut. Sulphate of lime is found in veins in the form of beautiful fibrous gypsum, semi-transparent, and colourless. It also occurs in plates. Specimens of all the minerals here described, I have in abundance in my own cabinet—they have been mostly collected for me by Dr. Malcolmson, Mr. Mayers, and Mr. Adie, the duration of my own visits to Aden precluding me from procuring the rare minerals. [The following authors have been consulted in preparing these observations:—Bruce's Travels. Lands of the Bible by the Rev. Dr. Wilson, vol. Wellsted's Memoir on the coast N. of p. 19 Aden. M. D'bbæ's account of p. 12. Buist, Dr. on specimens of lava from—Bombay As. Trans. vol. I. p. 345 size of, compared with Ætna. Remarkable currents in Gulf of, betwixt to Arabian African shores, Haines in Lond. Geog. Trans. 1848.—supposed to arise from the influence of the winds, or variation in the character of the water in the Red Sea. Discovery of Fluor Spar in lava of, Dr. Girandon.] Right across the bay to the eastward, at a distance of five miles are the magnificent remains of another crater, called Gibbel Hassan. It is nearly the same size and form as Aden, but rests on the mainland. The centre peak attains an altitude of 1237 feet, and on sailing round in certain aspects it presents the appearance of a stupendous Gothic cathedral; two peaks of 700 feet, close beside each other, have obtained the very unpicturesque name of the Asses' Ears, from the appearance presented by them far out at sea: seven miles beyond this, and seventeen from Aden, another fragment of a cone of smaller size, but considerable beauty, rises up to the altitude of 700 feet and projects about three miles into the sea, while half-way betwixt this and the Straits, Gibbel Kurrus or St. Antony, apparently a volcano, reaches an elevation of 1772 feet—Barren Peak and the high range of Gibbel Arrar, or the Chimney Peaks just opposite the Strait, being all set down by the surveyors as hills of volcanic origin. [The whole of this information is taken from the Charts and survey Notices of 1836-40. Aden is the only volcano I have myself examined—the others, I have merely seen from sea. They have all the appearance of being correctly described, and considering the ability of the surveyors, I have no doubt that they are so]

The range from this bends northward, and follows the line of the Red Sea shore.

From Aden to Babelmandel, indeed, the rocks along the Arabian shore seem to be wholly volcanic for a distance of above 100 miles. On the African shore a singular cove at the upper end of the Bay of Tadjoura, called Joobul Khareb, seems the crater of an old volcano; it is connected with the Bay of Tadjoura by two narrow channels the whole width across from coast to coast being about three quarters of a mile, with a small island near the middle. One of the channels is forty yards wide, with sixteen fathoms water, the other 250, with three fathoms. The cove inside is about thirteen miles in diameter, by six—the western portion is volcanic. At its extremity is a basin, or crater, 300 yards in diameter, surrounded by precipitous volcanic cliffs through which the sea makes its way to the water inside, the entrance is dry at low water.

Lava and scoriae abound everywhere around. [Capt. Barker's paper. Lond. Royal Geograph. Trans. 1848.] The waters of the cove are said occasionally to be violently agitated and disturbed without apparent cause, probably by the emission of gas from below [Harris, Highlands of Ethiopia. vol. I. p. 17.] The volcano being scarcely yet asleep. Off the outer bay, the hills are of limestone, and rise to the height of 2000 feet.

The rocks around the salt lake Assal, whose waters are now nearly dried up and encrusted with salt, are all volcanic on the eastern side. A bed of lava, containing several deep fissures, separates the waters of the lake from those at Gubatel Kherab, of which it appears to have been a continuation. [Dr. Kirk's Journey from Tadjoura Ankobar, 1841. Geolog. Trans. 1841. vol. X. The paragraph is given verbatim. Ibid, and more extended, Bombay Geogr. Trans. vol. VI, 1841 to 1846.] The lake is  $11^{\circ}38'12''$  N. and  $42^{\circ}30'6''$  E., it is about seven miles across in its larger diameter, and 570 feet below the level of the Sea. For about 300 miles westward into the interior the whole country seems volcanic.

To the south-westward of this near Shoa, is the volcano of Gibbel Abida, about 4000 feet high, its crater opening to the N. W., and about two and half miles in diameter, and further on the still higher peak of Aiullo. Here there is an even plain about thirty miles in diameter, studded with small cones, of which as many as twenty may be counted at once, each exhibiting a distinct and well found crater. The lava everywhere around is fresh and glossy but no tradition exists of any eruption having occurred within the memory of man.

Returning to the Straits of Babelmandel, we find the volcanic peaks of the High Brothers, just outside the gut, on the African shores. The Island of Perim, which occupies a portion of the Straits near the Arabian side, with the Babelmandel Peak on the mainland close by are masses of lava. Along the African shore, from lat.  $11^{\circ}$  to lat.  $14^{\circ}$  and from long,  $42^{\circ}$  to Long  $44^{\circ}$  the series of volcanoes is uninterrupted for the space of 400 miles running into the interior about  $10^{\circ}$  N. towards Ankobar, long  $40^{\circ}$  E. [Dr. Kirke, ut sup.] How far the volcanic district extends into the interior along the African shore within the Straits of Babelmandel does not appear—a range of hills above fourteen miles from the sea to which it is nearly parallel is set down on the chart as mostly volcanic: there is a second chain of very high mountains parallel to this again, about fifty miles further to the west, but its character does not appear to have been ascertained.

On the Arabian shore from lat.  $30^{\circ}$  to lat.  $15^{\circ}40'$  for a distance of nearly 200 miles a range of hills of volcanic origin is set down on the map about twenty miles

from the shore, with a second range behind them, like that on the African side undescribed. The lower range is a continuation of the Aden volcanoes; thus extending in a continuous line for above 300 miles along shore. There can be no reasonable doubt that the whole basin of the Red Sea,—here about 100 miles across,—from the Arabian to the African chain of peaks, is volcanic, studded as the intermediate channel is with cones now in a state of activity so that the *ascertained* area of this region from Aden to near Ankobar, and from this to Gibbel Teir is about 350 from E. to W. and 450 from S. to N. Within the channel of the Red Sea the most conspicuous peaks are the Harnish Islands, and Gibbel Goo-gur, betwixt lat  $13^{\circ}40'$  and  $14^{\circ}$ , the Zebeyar Islands in lat.  $15^{\circ}$  and Gibbel Teir in lat.  $15^{\circ}30'$ . A violent eruption of short continuance occurred in the Zebeyar Islands on the 6th August 1846. Gibbel Teir has for nearly a century been known to be in a state of constant activity. It was visited by Bruce in 1774; it then gave out smoke, and was said occasionally to emit flame and stones; he describes the masses of lava as having shells embedded in them, a circumstance that has not, so far as I have observed, been noticed by any other traveller. [See Travels, quoted in Geographical Society's Report for 1850.] It was visited by Capt. Elman when engaged in survey in 1838. [I have taken Dr. Kirk's description, slightly abridged.] And by Dr. Kirk in 1841. The island is circular about seven and a half miles round. [Dr. Kirk makes 300, Bruce 500; in the survey charts it is set down at 900.] Resembling on being approached, a hill of considerable elevation rising from a plain terminating in a bluff steep on the eastern extremity. The summit of the hill is about 300 feet above the sea level.—there are no soundings close in shore, at  $150^{\circ}$  fathoms, so that the visible portion is merely the summit of a hill the base of which is hid by the water in all probability 1,109 feet high, or 1,900, if the altitude of 900 assigned it by the chart be correct. The whole surface is covered with ashes, lava, and cinders; near the summit there are about fifteen small open craters, from several of which steam and hot air are continually issuing and occasionally smoke. Streams of indurated lava are seen to proceed from these chiefly towards the east side of the island. It is said to have been on fire about 1828 or 1830. One of the peaks in which it terminates exhibits the remains of two craters of about twenty five feet in diameter—both have fallen in: a single crater of much more recent formation than the others appears in the Northern peak of Gibbel Teir, it seems the northernmost of the volcanoes in the Red Sea, and probably limits the band.

We have no information whatever, so far as I know, as to any volcanoes in the interior of Arabia, or to the Northward. An extinct volcano,

## VOLCANOES OF INDIA.

called Mount Nimrod, is described by Mr. Chancourtois. [Report of the Academy of Sciences 17th Nov. 1845.—Ibid. Edinburgh Philosophical Journal, April 1846. p. 377, as existing near the Salt Lake Van in Armenistan, on the frontiers of Persia, between the 38th and 39th degrees of latitude. On the banks of the Euphrates, near the city of Hit, in the region of the Petroleum Wells, Dr. Winchester found scoria on the summit of a detached hill about eighty feet above the level of the plain; no other volcanic appearances was observed. [Bombay Geographical Transaction, vol. II. p. 30.]

The following, on the supposed burying of great cities in Central India, is extracted from the 8vo. edition of "Lyell's Principles of Geology, 1832"—it is transferred unaltered to the edition of 1851:—

"We remarked in a former volume, that in many countries which have been peopled from remote ages by civilized nations, and have been at the same time the theatre of volcanic action, there must be innumerable monuments of the highest value to the historian, which continue unobserved 'because they have not been searched for.' But we omitted to describe in detail a splendid example of several buried cities in Central India, which might probably be made to yield a richer harvest to the antiquary than Pompeii or Herculaneum. [Ibid. p. 407.] The city of Oujein (or Oojain) was, about fifty years before the Christian era, the seat of empire, of art, and of learning, but in the time of the Rajah Vicramaditya, it was overwhelmed, together, as tradition reports, with more than eighty other large towns in the provinces of Malwa and Bagur, 'by a shower of earth.' The city which now bears the name is situated a mile to the southward of the ancient town. On digging on the spot where the latter is supposed to have stood, to the depth of fifteen or eighteen feet, there are frequently discovered, says Mr. Hunter, entire brick walls, pillars of stone, and pieces of wood of an extraordinary hardness, besides utensils of various kinds, and ancient coins. Many coins are also found in the channels cut by the periodical rains, or in the beds of torrents-into which they have been washed. "During our stay at Oujein, a large quantity of wheat was found by a man digging for bricks. It was, as might have been expected, almost entirely consumed, and in a state resembling charcoal. In a ravine cut by the rains, from which several stonepillars had been dug, I saw a space from twelve to fifteen feet long and seven or eight feet high, composed of earthen vessels, broken and closely compacted together. It was conjectured, with great appearance of probability to have been a potter's kiln. Between this place and the new town is a hollow, in which tradition says, the river Sipparah formerly ran. It changed its course at the time the city was buried, and

## VOLCANOES OF INDIA.

now runs to the westward. [Narrative of a Journey from Agra to Oujein, Asiatic Researches, vol VI. p. 36.] The soil which covers Oujein is described as being of an ash grey colour, with minute specks of black sand [Asiatic Journal, vol. IX. p. 35.

"That the shower of earth which is reported to have fallen from heaven, was produced by a volcanic eruption, we cannot doubt, although no information has been obtained respecting the site of the vent and the nearest volcano of which we read, is that which was in eruption during the Cutch earthquake in 1819, at the distance of about thirty miles from Bhooj, the capital of Cutch, and at least three hundred geographical miles from Oujein.

"Captain F. Dangerfield, who accompanied Sir John Malcolm in his late expedition into Central India, states that the river Nerbuddah, in Malwa, has its channel excavated through columnar basalt, on which rest beds of marl impregnated with salt. The upper of these beds is of a light colour, and from thirty to forty feet thick, and rests horizontally on the lower bed, which is of a reddish colour. Both appear from the description to be tuffs composed of the materials of volcanic ejections, and forming a covering from sixty to seventy feet deep overlying the basalt, which seems to resemble some of the currents of prismatic lava in Auvergne and the Vivarais. Near the middle of this tufaceous mass, and therefore at the depth of thirty feet or more from the surface, just where the two beds of tuff meet, Captain Dangerfield was shown, near the city of Mhysir, buried bricks and large earthen vessels, said to have belonged to the ancient city of Mhysir, destroyed by the catastrophe of Oujein." [Sir J. Malcolm's Cent. Ind.—Geol. of Malwa by Captain F. Dangerfield. App. No. II. pp. 324.] Lyell's Principles of Geology, 1832. pp. 237-38.

I have not had it in my power to visit or examine this part of India, and can only speak of it on the authority of others. I am from this strongly inclined to believe, that the tradition of the shower of earth is wholly fanciful, and that the assumption of the submergence of the cities in Central India wants conformation. It is quite clear from the expressions made use of, that both Capt. Dangerfield and Sir John Malcolm speak mainly on the authority of Mr. Hunter: the latter writes with the utmost hesitation, and both at best are but hearsay witnesses. The following are the words of Capt. Dangerfield in reference to Mhysir, from which it will be at once seen that he believed the earthy mass on the banks of the Nerbudda alluvial, not volcanic.

"At present there is no appearance of volcanic matters, though some of the hills, both in the Vindhya range and in the neighbouring wild tract of Raisenly, are said to have hollows some-

times filled with water, near their summits, which have been thought to resemble extinct craters. These I have never seen, and cannot, therefore, hazard an opinion. Earthquakes appear to be, to the Northwest, of frequent occurrence, and, if we may judge from the recent one which nearly overwhelmed the province of Cutch, often very severe. These soils are sandy, and with their saline ingredients appear, however, naturally enough to be derived from the decomposition of the rocks composing the neighbouring mountains, and which each rainy season, with the violence peculiar to India, would bring down and deposit in great abundance. But how the two strata have acquired their relative position and marked line of separation, it is here unnecessary to surmise or inquire."—(App., No. II, to Sir J. Malcolm's Memoir of Central India, p. 325.)

Conolly, on the other hand, speaks from careful and minute personal observation, he being one of the most exact and observant writers of his time. There are others who write to exactly the same effect with Conolly, though I am not at present able to cite them. It is a sad reproach to our Government that with such abundance of men of talent and research at their disposal, facts so interesting and important as these should remain in dubiety: even the Neapolitan government charges itself with the investigation of the antiquities of Herculaneum and Pompeii.

"The theories which account for the change of site of Oujein appear to me all equally unsatisfactory. I neither believe with Hunter that a shower of earth nor with Malcolm that a flood, overwhelmed the old city, nor with the natives that it was turned topsy turvy. The tales of old bricks, and of wood of surprising hardness, &c. dug up at depths of fifteen feet seem to smack of the Oujein failing of exaggeration. Several people were interrogated who had been twenty and thirty years at the place, none of them had ever positively seen such things though all believed most religiously both these and much more wonderful curiosities to be found. It is currently told, that a chamber was discovered in which was seated the skin of a beautiful lady just, explained my informant, like the shape of a grasshopper which you see trembling on a stalk of grass in the dry weather. Some incautious visitor approached too near the delicate shell, it vanished into air—like the fish found in the pyramids,—*comme-de la pousiere quis' envole quand au souffle dessus.*' Bricks found at any depth would prove little, for they might have belonged to walls which stood on the slope of a hollow, filled up by time; many of the houses of the present town being built in this fashion to save the trouble of making a back wall, or they might have belonged to under ground granaries *tahkhanehs*, or wells. A shower not exactly like the famed one of bricks and tiles, [Phiny, where the date is gravely given.] but one equally composed of

building materials, such as rained, says Assemani, in 769, 'Une pluie de pierres noires; seems as likely to have fallen here, as earth or sand.

"The surface of the hill (of the old city) where it has not been ploughed and picked is strewn with fragments of stone, just as you would expect in a place which had once been covered with houses: these broken pieces of trap being parts of walls of which the larger companions have been taken away as materials for other buildings.

"The theory of an inundation is principally supported by a tradition that the river has changed its bed. This belief seems to me a native fabrication to account for a square, tall, brick building, which resembles the wells so frequently found near the banks of the river. It is situated in a hollow, through which the river is said formerly to have flowed, and which is perhaps merely the dried up channel of some nullah. Of the name of the well Bibi Mako I could get no more satisfactory explanation than that the words are convenient for the repetition of the echo. Every little idle urchin runs into the square and bawls out Bibi Mako with a drawl on the O, and is equally frightened and delighted with the reply of Bibi Mako. One argument is conclusive against an inundation: that the hills on which stood the old city are higher ground than the level of the present town, and that the latter is the more likely also to be overflowed. Indeed no such extravagant theories are required to account for the desertion of the first occupied spot. The whim of the reigning prince is sufficient to determine the position of any oriental town, of which we cannot look around without observing instances, as at Delhi, Lucknow, Maheswar, &c. And that coins and antiques should be picked up is not a whit more extraordinary than the annual harvest of such curiosities at Begharm and Canouj, &c., towns, the last of which at least, was gradually deserted.

"Romance lovers would be shocked at my theory of the origin of the so-called raja Bhirtri caves. The natives are in the habit of excavating the foot of the hills of the old city for an excellent clay of which there is a thick and extensive bed. Any one who has resided at Delhi will remember the excavations there for the same purpose, which have not unfrequently been converted into agreeable *tahkhanehs*. One of those of Oujein nearly rivals in extent Bhirtri's retreat, is supported by arches cut out of the clay and is divided into several chambers. Such was probably the origin of the great caves, which are very low, and not of any great extent. [The dimensions may be seen in Hunter.] They are supported by pillars, clumsy, but massive, and the walls and ceilings are lined with enormous blocks of stone calculated, it might be thought

## VOLCANOES OF INDIA.

"to fatigue time." But they will shortly be crushed by their own weight; already one room has fallen in, and some of the slabs are in such a position that at first sight it does not seem safe to walk under them. What may have been the primary object of the buildings is matter of question. The natives contend that it was raja Bhirtri's hermitage, but their own fables refute them, for we read that the raja immediately after swallowing the amar phal set out on his travels. In no place did he allow his weary limbs long to rest, though he halted at Sehuan on the Indus, at Bhartewar near Khyroda, at Chunar and Benares, and to this day he is believed to be still wandering about, among the Hyperboreans beyond the Himalayas. A late writer, [The author of the paper before alluded to in the E. I. United Service Journal,] imagines it to have been the dwelling place of raja Bhirtri. There is, however, no appearance of its having been built to live in. Bhirtri, would have run the risk of breaking his head or his shins every time he rose up, or walked, in his low roofed unevenly floored mansion. The caves seem by their position to be exposed to inundation, which alone would have unfitted them for houses, and may have been the cause of their having been solidly built. An outer court, though very strongly constructed has been partly thrown down apparently by the swell of the river. The pillars too are sculptured on only three sides, that side which faces the wall, and which would not be seen by one passing through the caves, not having been even smoothly chiselled.

According to Colebrooke's theory, which however seems to have now but few followers, "the antiquity of the caves will be much lessened, if from the first they were furnished in the same fashion as the present, for they are now evidently ling temples. The figures on the pillars, are small, much defaced, and were originally far from being deeply carved, but there is no difficulty in recognizing them for those indecent groups which mark the temples of Siva. Several lings are scattered about, though one only seems to be worshipped at Kedareswar, 'lord of cedars.' Marks of feet engraved on the rock are not unfrequent. At the end of the left cave on a slab of black stone about three feet high, one broad, two figures (one over the other), are cut, sitting cross-legged, performing topasya. The upper one is called Gorakhnath, the lower, his pupil Bhirtri. "Near the entrance lies a huge head of a Rakeshasa, and the ghat below takes its name from a gigantic stone image of Kapila muni which leans against the bank half buried in sand."

"The quantity of antiques collected amongst the ruins of Indian cities has always seemed to me a subject of wonder. The supply from old Oujein is so constant and plentiful that the natives call the place by the appropriate name of

## VULPES FERRILATUS.

Rozaka Sâdabirtâ, and it is in truth a never failing charity for the industrious poor. In the idle days of the rains the digging begins. The principal things found are glass, stone, and wooden beads, small jewels of little value, seals, (agate and cornelian,) and a few women's ornaments; copper coins are numerous, next in number are the debased silver Guzerati ones. Pure silver rupees seem scarce, and gold mohurs are either secreted and melted when found, or they but rarely reward the searcher, for I was only able to procure one, and that a doubtful specimen. As the pilgrims carry away with them as relics, what has been dug out of the Jungarh, the merchants mix with the real antiques every old bead or piece of copper which has an ancient look, and pass them off as genuine on the unsuspecting natives. One man brought a large heap of copper seals or plates of chaprasas which had engraved on them modern Musalman and Mahratta names, and was ready to take his oath that they had been dug up, which perhaps they were, for he had probably buried them that they might have the appearance at least of age. Steatite 'Nadalis' are also frequently brought for sale, some of them as old looking as if they had really been buried with the city." —*Journal of the Asiatic Society of Bengal*, p.p. 851-54.

Dr. Buist in Trans. Of The Bomb. Geogra. Soci. Pages from 139 to 767.

(2955) VOLCANO OF TAEI is in the island of Luconia in Manilla. The island is formed by a mountain from three hundred and fifty to four hundred yards above the level of the Laguna de Bombon, is about three leagues in circumference and has a crater about 2 miles at its circumference on its summit. The lining walls of the interior are fifty to seventy five yards in perpendicular height and five cones of eruption covered with sulphur rise from the centre of the crater, a lake of green water which boils in several places. The Laguna de Bombon, itself has a circumference of thirty leagues; its waters are brackish and bituminous, and of great depth, in some parts no soundings at 125 fathoms. The great eruptions occurred in the years 1716, 1746, & 1754. —*Elder's Biography of Dr. Elisha Kent Kane*, 1858.

(2956) VRITRA, otherwise called Ahi, in Hindu mythology, the personification of the rain-cloud; with whom Indra, the lord of thunder had a contest. —*Thomas' Prinsep's, Antiquities*.

(2957) VULPES BENGALENSIS, (Shaw): *Canis Kokree*, Sykes: *C. rufescens*, *V. chrysurus*, et *V. xanthurus*, Gray: *V. corsac* apud Ogilby. India generally, but not Ceylon.

(2958) VULPES FERRILATUS, Hodgson. Tibet. Lt. Speke, of the 46th N. I. informed Mr. Bligh that he is familiar with three species of Foxes in Tibet: two of which he identified in the

## VULPES LEUCOPUS.

Museum with Nos. 1 and 7, and the third he stated to be more like No. 6;—doubtless, therefore, the true *corsac* of Pallas, which according to Dr. J. E. Gray “is very similar to *V. Bengalensis*, but differs in having no grey collar round the front of the chest.”

(2959) *VULPES GRIFFITHII*, Bligh, *n. s.* The ordinary small Fox of Afghanistan (vide *J. A. S.* XIX, 344). Size of last, or larger than *V. Leucopus*, with longer fur, and the pale parts tinged with yellowish fulvescent.

(2960) *VULPES LEUCOPUS*, Bligh *supra*. The small desert Fox of W. India. The small desert Fox with white-tipped brush (*Vulpes Leucopus*, Bligh, XXIII, 729), is common in the neighbourhood of Hansi during the cold weather only, and very rarely seen there at other seasons.—*Journal Beng. Asiatic Society*, No. V of 1856. It is a typical *Vulpes* which *V. Bengalensis* is not; of the size of *Bengalensis*, or smaller than *Pusillus*.

This little Fox pertains to a species hitherto undescribed and merely vaguely indicated, which I have long sought to verify.

The Honorable Mountstuart Elphinstone remarks of the Foxes of the great Hurriana desert, that these “are less than the English Fox, but somewhat larger than the common one of India: their backs are of the same brownish colour with the latter; but in one part of the desert, their legs and belly up to a certain height, are black, and in another, white. The line between those colours and the brown is so distinctly marked, that the one kind seems as if it had been wading up to the belly in ink, and the other in white-wash.” (*Account of Cabul*, &c, p. 7) Mr. Walter Elliot would not appear to have discriminated this small Fox of W. India from *V. Bengalensis*; further than by the observation, that—“It is remarkable that though the brush is generally tipped with black, a white one is occasionally found, while in other parts of India, as in Cutch, the tip is always white.” (*Madr. Journ.* X, 102.) We have little doubt that Mr. Elliot’s supposed variety of *V. Bengalensis* with white-tipped tail, refers to the present species: but Mr. Griffith’s smaller Fox of Afghanistan (*J. A. S.* x, 978,) is different, and so we now consider Mr. Theobald’s small Fox of the Punjab salt range (*J. A. S.* xxii,

## VUTTA THAMARY.

531,) to be, and this may bear the appellation *V. Pusillus*. The small desert Fox of W. India may be designated *V. Lencopus*.

The following is the series of Indian and Tibetan Foxes now in the Museum of the Society.

(2961) *VULPES MONTANUS*, Pearson: *V. himalaicus*, Ogilby. Like the British *V. Vulgaris*, but always much less rufous, paler and more hoary; specimens varying, however, a good deal in colour. Common in the N. W. Himalaya, as about Simla and Masuri; and the larger Fox of Afghanistan was thought to be identical with it by the late Mr. Griffith.

(2962) *VULPES NIPALENSIS* (et *flavescent*), Gray: *V. montanus* apud Hodgson, *passim*. Described *J. A. S.* XI, 589. The common large Fox of Tibet, rarer S. of the snows, and believed by Mr. Hodgson to be *V. Montanus* until we shewed him the identical specimen upon which the latter was founded by the late Mr. Pearson. In Dr. Gray’s printed catalogue of the specimens presented by Mr. Hodgson to the British Museum, *V. Montanus* apud Hodgson is identified with *V. Flavescent*, Gray; but it differs much from the small Afghanistan Fox which we have hitherto referred to *V. Flavescent* (vide *J. A. S.* XIV, 314). This handsome species is of the size of *V. Vulgaris* and *V. Montanus*, but has much finer, longer, and denser fur, of a prevailing bright light yellowish fulvous colour, with correspondingly superb brush, and the black ears strongly contrasting. The Society’s specimens are from beyond the snows.

(2963) *VULPES PUSILLUS*, Bligh. The small Fox of the Punjab Salt Range. Nearly resembles the last, except in being a much smaller animal.

(2964) *VUTTA THAMARY*. A simple pure gum of a crimson colour from Travancore: it has been used for taking impressions of leaves, coins, medallions, &c. Specimens of the transparent castings are forwarded; when the gum is pure and carefully prepared the impressions are as sharp as those of sulphur, without its brittleness—also a twig of the tree, which has been identified as *Macaranga Indica*, the exudation so far as known is an entirely unknown production.—*M. E.* of 1857.

## W.

(2965) WANDEROO MONKEY, *Macacus silenus*.

(2966) WAX, VEGETABLE. This term has recently been applied to solidified oils. Mr. Edward Loarer lately discovered a mode of fabricating, so as to become a mercantile product, a substance which until that time had been of no commercial value. This substance he named vegetable wax, from its resemblance to that animal product, and he obtained a Patent for it under Act VI of 1856 of the Government of India.

Since then, he has manufactured about 200 tons of that material, all of which has been sold, in Madras, Calcutta, and Europe; it has brought various prices, but the latest selling price at Havre was about £43 per ton of one thousand kilogrammes, or 2,200 English pounds. The Patent Act of 1856, was repealed by Act IX of 1857, and his Patent rights fell into abeyance, but under Art. 35th of the new Act, these have been recovered by him and the right of manufacturing and selling the product, again became his own.

Candles can be prepared of the same material; and advices from Bordeaux shew that the power of bleaching it is possessed in Europe. The vegetable wax is made from the common lamp oil (castor oil) of the country, the plant producing which, is grown throughout the length and breadth of the Indian Empire, springing luxuriantly even on bare rocky soils, affording, therefore, exhaustless supplies of the raw material for the wax.

During 1856 and 1857, Mr. Loarer's success in the manufacture and sale of the vegetable wax was so great, that he almost acquired a modest competency, and thinking the knowledge how to manufacture this product, if widely spread would add one more source of profit to the people, he offered to impart all his knowledge and dispose of all his exclusive rights for the sum of Rupees 5000 undertaking to teach for the next three months and fully instruct any number of servants or subjects of the State. This offer was for the twenty-two Civil Districts of the Madras Presidency, only, reserving for his own benefit the new Patent Act in the other parts of the Indian Empire.

Before coming to any decision on the subject, the Government in Extract from the Minutes of Consultation in the Public Department, dated 24th August 1858, No. 1057, resolved to refer Mr. Loarer's offer for the opinion of a Committee composed of the following Officers, viz., Colonel A. McCALLY, Colonel G. BALFOUR, C.

B. Lieutenant Colonel F. C. COTTON, J. E. MAYER, Esq.

This Committee was constituted for reporting on the produce and resources of India, and satisfied themselves by enquiry, that, excepting in connection with Mr. Loarer, vegetable wax had not hitherto been found amongst the Indian exports as an article of commerce, nor entered among the lists of exports from any part of India; and that in the solidified form in which presented by Mr. Loarer, it may therefore be considered a new article of India trade.

The filed specification held by Mr. Loarer, sets forth several processes for converting certain oils into a solid substance, named vegetable wax; but the Committee tested two processes, by causing experiments to be made on the limited scale to which chemical book accounts apply, and on the extensive, simple, and economical scale, which Mr. Loarer considers peculiarly valuable in his processes.

In the experiments both of Mr. Loarer and Mr. Norton the former produced vegetable wax with great economy in the use of the chemical ingredients, and employed them in such a mode as to satisfy the Committee by a careful calculation of the cost of the conversion, that Mr. Loarer's process is of a far more economical nature than that described in Chemical works, as the following comparative calculation will shew.

In experiments 1, 3 and 4 by Mr. Norton the quantity of nitric acid used, was one twentieth part of the oil experimented upon; at which rate the cost of manufacturing ten tons of vegetable wax would be as below: 22,400 lbs. of oil would require 5 per cent of nitric acid viz., 1,120 lbs.

	RS.	A	P.
1,120 lbs. of nitric acid @ 1 Rupee a pound,.....	1,120	0	0
Coolies for stirring.....	1	0	0
Cost for ten tons,.....	1,121	0	0
For one ton,.....	112	1	6
But by Mr. Loarer's process No. 1, the cost is per ton only,...	4	4	0
And by process No. 2, is only	1	11	3

Mr. Loarer's experiments in presence of the Committee were on a scale so large as to enable them to report with confidence as to their successful application to any quantity, and doubtless with yet more economy if on a very extensive scale.

By one of Mr. Loarer's processes, extremely simple, about 100 lbs. of oil were congealed in 8 hours; only one ingredient (sulphuric acid), in

## WAX, VEGETABLE.

any way difficult to procure in the country, was used, and that only in very small quantity sixteen ounces sufficing for obtaining 100 lbs. of vegetable wax. This process is admirably adapted to the country and may be adopted by the ryots without any difficulty; for although sulphuric acid cannot be manufactured at present in the interior, it is cheaply prepared at the Madras Mint (at 2 Annas per lb.) and is not difficult of carriage.

The next process, in which both nitric and sulphuric acids are used, is the best adapted for manufacture on a large scale; by this process 400 lbs. of oil were congealed in a wooden trough in 4 days, and Mr. Loarer has suggested an arrangement, and described an apparatus, which would make this process of preparing vegetable wax on any scale, very simple.

The Committee had therefore no hesitation in reporting that the manufacture of vegetable wax can be generally introduced into this country; thus enabling the grower of Castor and other similar Oil Seeds to carry oil to market in a solid and consequently more portable state: and with the diminished cost of carriage, the growers from the interior might advantageously sell their produce on the Coast, or export it to foreign countries, whereas at present the carriage of fluid oils is not only difficult, but costly.

The vegetable wax may be applied to several uses and when this product is fairly tried and introduced into England, it will take its place there amongst the most valuable imports.

Any new oily substance so economically manufactured as the vegetable wax, is sure to be applied to many important uses; and as it will undoubtedly compete, successfully as regards cost, with the cheapest oil or fat now employed in England, there can be no doubt as to the result. Even in India, Mr. Loarer has made a considerable profit upon the vegetable wax, having sold some to the Madras Railway for use, and some to other parties for export to Europe; and the Committee have no doubt that with the great reduction in price which Mr. Loarer anticipates being able to make, the article will speedily overcome temporary objections.

The Lamp oil and Castor oil seed plant is grown in all parts of the country and on the poorest soils, the arid nature of the country, and the climate of Southern India being particularly suitable for its growth; and Mr. Loarer's cheap process of converting the oil into wax, will, by enabling the Ryot to store the solid substance far more easily than the seed or fluid oil, lead to the oil being expressed from the seed whilst clear and free from impurities: and its utility being thus increased, the export of vegetable wax will probably increase as rapidly as did that of gingely oil seed, when the fact was once established, that the oil it yields was applicable to the same purposes as olive oil.

## WAX, VEGETABLE.

The vegetable wax has the advantage of being easily stored, and transported from the interior on the rudest conveyance and in the simplest and cheapest form; it can be loaded upon carts, on bullocks, or in any way best adapted to the habits of the people, and sufficiently protected from injury and from weather by the ordinary leaves and mats of the country, requiring neither casks, dubbers, nor boxes to convey it. It can further be solidified into any portions or shapes, and on board ship can be stowed in any convenient corner; requiring no protection against leakage or bilge water, and by its nature it can be packed so close, that no danger from shifting of cargo or injury to the article from rubbing, need be apprehended.

The Ordnance and Public Works Departments, in this country will readily find many uses to which the article can be applied, and doubtless practical experience and time will extend these uses. The Railway Authorities have already purchased the vegetable wax to a considerable extent for lubricating; and when once the sale is open, the price of the article will be very low, and the Officers of the Railway will be enabled, by mixing with it other substances, to render it suitable for the purpose of grease, at a very small cost. The recipes for preparing the Railway grease employed in England and in Belgium, require soda water, oil, and suet or tallow, combined in certain proportions; whereas Loarer's vegetable wax if used as the lubricating agent to form the main ingredient in the composition would, at the rate at which it could be purchased in an open market, allow of a considerable saving in the present outlay for grease for Railways; and at the same time, an article would be obtained, which the experienced Manager of the Rail considers to be superior to all other mixtures as a lubricate. The consumption of tallow and fat in the Madras Ordnance Department in the year 1857-58 was 10,772 lbs. at an outlay of Rupees 3,989; and taking the highest price of oil, viz., 60 Rupees per Candy of 500 lbs., the price of the above quantity of tallow and fat is about three times the cost at which an equal weight of vegetable wax can be prepared by Mr. Loarer's process; and if used for only some of the purposes to which fat is now applied, a considerable saving would be effected by the introduction of this substance. The large consumption of grease at the Railway would also give a considerable margin, in favor of the vegetable wax.

Looking to the extensive benefit to be derived by the people of the country from a knowledge of this mode of obtaining vegetable wax, by bringing into practical and extensive demand the most common article of produce in this country, (oil) the cost of which will by Mr. Loarer's discovery be diminished in various ways, and considering the vast pecuniary interest the Govern-

## WAX, VEGETABLE.

ment of this Presidency has in the extension of cultivation and the increase of useful exportable articles, by reason of the direct revenue drawn by Government from the lands of the country, the Committee recommended the sum of rupees 5,000 to be paid down to Mr. Loarer, and Rupees 5,000 more to be paid on 500 tons of vegetable wax being exported; The Committee recommended further, that it at any time within 20 years, 5,000 tons of castor or other oil in a solidified form be in any year exported from the ports of Madras, an additional sum of Rupees 5,000 be granted to Mr. Loarer, or his heirs.

Mr. Loarer gives the following accurate details of three different processes for the manufacture of vegetable wax.

### 1ST PROCESS.

This is the cheapest of all, and is well adapted for villagers and ryots. A common earthen pot being the only apparatus necessary.

Take one part of common unrefined Saltpetre, and one part of Sulphuric acid: mix these at the bottom of a pot of sufficient size, and as soon as the mixture is well saturated, a hundredth part of common Castor oil is to be slowly poured upon the mixture, and the whole heated on a slow fire until it reaches a temperature of  $\frac{2}{3}$  that of boiling water or about 160° Faht. (more or less is not the question provided the oil does not boil). The means for ascertaining the temperature of the oil is with the finger, being careful to stop the fire so soon as the heat will not allow to keep the finger into the oil: the compound is then allowed to cool and may be then decanted into another pot or box made water-tight and it is then well stirred when it begins to thicken. This process will last about 8 hours and the cake will come out of the mould three or four days afterwards, in a hard lump ready for packing into plantain leaves and gunny bags; square boxes of 18 inches on every side, are the best things for moulding, but at least one of the sides should be moveable, to facilitate the exit of the cake when it hardens. He strongly recommends an active stirring when the paste thickens, as it betters the color of the vegetable wax.

Washing the cakes when they come out of the moulds is very useful for taking away all viscosity—if the cakes are left in the moulds eight or ten days it will be better.

The cost of manufacturing a ton of 2,240 lbs. of vegetable wax, not including the price of 2,240 lbs. of oil is as follows.

20 pounds of crude saltpetre,....	Rs. 1	4
20 pounds of sulphuric acid,....	„ 2	8
Fuel,.....	„ 0	2
Coolies for manufacturing and		
packing, .....	„ 0	1

Total Co.'s Rs... 4 6

Mr. Loarer prefers crude saltpetre to refined nitre, as the former yields by its combination

## WAX, VEGETABLE.

with the sulphuric acid, a notable quantity of chlorine, which has a bleaching property on the wax; more, it is cheaper.

### 2ND PROCESS.

For a large manufacture the above process would become tedious because it is difficult to procure pots of 20 gallons, the pots are very often broken, entailing a great loss in raw materials and the pots will hardly stand more than eight or ten operations, being very soon corroded by the bi-sulphate of potash formed during process.

The plan of a plant for manufacturing ten tons at every out-turn would be as follows:

A large vat or tub made to contain two thousand gallons, having at two inches above the bottom a number of holes with leaden pipes for drawing out when required, the contents of the vat.

An iron retort in the form of a gas cylinder with a hole—in the centre of the cover of the hole is a small aperture half an inch in diameter for pouring in the acid—this small hole may be stopped with baked clay or wood.

Leaden pipe connects the still with the bottom of the vat.

Many moulding boxes, with one moveable side and moveable diaphragms; distant one from another 18 inches and dividing the boxes into an exact number of cubic cells 18 inches on each dimension.

This machinery being ready, the vat being full of oil, the retort will receive a load of *seven pounds* of crude nitre for every *thousand pounds* of oil in the vat—the hole must then be well secured and luted and the sulphuric acid is poured upon the nitre, through the small aperture using a funnel with a long neck: the small aperture is luted or stoped, and fire is kindled under the retort (Note.—To every pound of crude nitre allow a pound of commercial sulphuric acid); first a slow fire, then a very brisk one should be applied during two or three hours, the oil in the tub will become gradually heated till it reaches 120 to 130° Faht. when the evolution of gas is no more perceptible in the oil, the stopper should be opened and the fire taken out of the grate.

The whole is allowed to cool during the night, and next morning a light film much like cream on the top of milk, is perceptible on the top of the oil, it is then time for opening the holes: the liquid is let into the moulding boxes, where it must be actively stirred as it thickens, as long as the magma will allow a strong man to stir it. The diaphragms are then inserted into the moulding boxes and the whole is left to itself for five or six days, the boxes may then be opened, the diaphragms removed, the cakes taken out, washed, allowed to dry for one or two days on platforms, and then packed in plantain leaves and gunnies.

## WAX, VEGETABLE.

If the moulding boxes are made of partitions exactly of 18 inches cube, each mould will weigh 225 pounds, ten packages to the ton, and very convenient for stowing on board.

### *Cost of ten tons by 2nd Process.*

155 pounds of crude nitre,.....Co.'s Rs.	6	0
155 pounds of commercial sulphuric acid,.....	10	0
Firewood, .....	0	8
Coolies, working and packing,....	1	10

Cost of manufacturing 224,000 pounds  
Total...18 2

or per ton... 1 13

### 3RD PROCESS.

A large vat, square or round, being made of wood or sheet iron must be supplied with a fan horizontal or vertical, the bottom of the vat must be calculated so as to leave no corner unstirred by the motion of the fan, the bottom of the vat must be well coated with a mixture of vegetable wax and rosin to preserve it from corrosion by acids, this being done, the vat is filled with oil and three quarters of a pound of nitric acid is put into the vat for every hundred pounds of oil contained in it, the mixture must be then well stirred by the fan, ten minutes for every two hours, until the oil becomes thick, viz., after three or four days, the composition should then be decanted into the moulding boxes and there stirred very actively (as in 2nd process.)

Note.—This process is very expensive compared to the first and second process, and should never be resorted to. The product from this process is improved by the addition on the second day, of one ounce of sulphuric acid for every pound of nitric acid, poured into the vat the first day, this betters the color of the wax and accelerates the result of the operation, but after all, this third process should not be resorted to, as long as it is possible to work the 1st and 2nd process.

### *Candle making.*

Candle moulds being prepared in the usual way with wicks and laid into the casting table, the oil prepared by one of the above processes, should be cast into the moulds, at the precise moment when the composition has reached the consistency of thick congee water.

The candles must then be left to themselves in the moulds, for five or six days, when they will come out with a fine gloss and a light saffron colour.

NOTE.—A very great improvement is obtained in the quality of the candles, by passing a current of chlorine gas through the oil during the process of solidification, when that is made with proper care, a threefold object is obtained :—

1st. Specific gravity increased and melting point raised.

## WAX, VEGETABLE.

• 2nd. Colour much improved.

3rd. The melted stuff never runs when the candle is lighted.

These candles are self snuffing, a very important item. It is as yet necessary to learn the composition of a good sort of wicks, before bringing these candles to perfection as an article for the million. There is at Calcutta a manufacturer of wicks on the French principle, and they sell wicks readily to every one who wants them.

Cost of 2,240 pounds of candles of vegetable wax :—

Four and half candies of oil @ 45 Rs.	
per candy, ... ..	202 8
Working of the oil into vegetable wax, (2nd process),... ..	1 12
Additional cost for chlorine, ... ..	1 0
13,440 wicks at 100 per Anna & cooly.	9 0
Other expenses, ... ..	0 8

Total..... 214 12

Cost to the manufacturer of one pound of candle 1 Anna and 7 Pies, or at the utmost 2 Annas per pound of candle.

Having described the manufacture of vegetable wax the following observations may be made on its mercantile value and its applications in the arts and industry.

Vegetable wax is an excellent lubricator, it has been extensively used on the Madras Railway. Mr. Fletcher the Traffic Manager wrote that he found Loarer's grease capital and they were then using nothing else.

It is in any ones power to make it of different degrees of consistency without lessening its high resistance to heat, it will answer when softer for any description of machinery, and will take with a notable economy the place of tallow so expensive for steam Engines.

Vegetable wax can be bleached perfectly white, and there was sent to the Exhibition of Madras in April 1857 a box containing some 30 pounds of vegetable wax bleached at Vellore, simply by exposure to the sun and dew, and, by keeping it continually sprinkled with water, three days of that treatment being sufficient for bleaching vegetable wax perfectly white.

Very good and cheap candles are made, immediately from the raw material, and without any chemical preparation whatever.

Vegetable wax can be converted into soap, and some tolerable samples of soft and hard soaps, have been made.

About a hundred pounds of vegetable wax was treated at Calcutta by a manufacturer of stearine candles, and it has been as easily converted into stearic acid as is the tallow by the

same process. The produce of tallow compared to vegetable wax was :

Tallow produce, Stearine 55, Oleine 43, loss 2.  
Vegetable wax „ 48, Oleine 48, loss 4.

The manufacturer of Calcutta said that with care and a more complete acquaintance with vegetable wax he would succeed in bettering the difference of produce between the two facts ; the price of tallow at Calcutta, varies from 12½ to 14 Rupees per Indian maund.

Vegetable wax is a very good substance for the preparation and keeping of all sort of leathers and hides, such as accoutrements for the army, harness, boots, ropes made of raw hides, &c., this substance never hardens, and never changes by exposure to the air, into a sort of varnish, rendering the leather hard and prone to cut, as is the case when tallow is mixed with oil. At home the tanner will find that stuff to answer as a succedaneum for more expensive oils, such as whale oil now in use. During the last three years Mr. Loarer used nothing else for the harnesses of his horses and it answered very well.

Vegetable wax is the cheapest material to be used for the preservation of all articles of iron of comparatively small value, such as bar iron, steel, Engineers and Artillery tools and spare pieces, the inside of guns, grape shot, &c., and in one word all articles of iron kept in store rooms and godowns, where they go to decay in so short a time—vegetable wax would equally do for round and hollow shot, but for the tremendous heat attracted by the black piles of shot in the Arsenals, in these tropical climates. It would prove superior to any coating now in use for shot, if the piles were only protected from the heat by the commonest sort of covering ; for ships of war where shot go so rapidly to decay the composition is capital. From vegetable wax never drying, it will never interfere with the progress of loading a gun, nay it would on the contrary facilitate its entrance into a foul gun.

Before affirming that this composition is good for the preservation of *small arms* and *polished steel*, it will be necessary to make long and accurate experiments, but it is recommended that the vegetable wax be melted into boiling water, so as to expel all excess of oxygen from the compound, and then it may be fit for use.

Vegetable wax being easily made of various consistency with a nearly fixed melting point, varying from 140 to 155° Fahr. it is the best thing for greasing the axles of gun carriages and waggons of the Artillery, Engineers and land transport corps.

The same substance may with great advantage and economy, be substituted in the studio of the statuary and the workshop of the moulder and casters in bronze or brass, to the bees wax which

is now very extensively used and costs about eight times more—a mixture of 8 parts of vegetable wax and two parts of bees wax is I think superior even to pure bees wax for ductility and evenness of grain.

Colonel Pears had no doubt that the vegetable wax would answer for the atmospheric Railways, he said that the only cause preventing the extension of the system, was the impossibility of finding a lubricating body, resisting a great heat and cheap enough for large workings.

Vegetable wax is a specific against white ants.

*Vegetable wax in a commercial point of view.*

Vegetable wax is manufactured from the coarsest sort of lamp oil, (Castor oil the produce of *Ricinus communis* v. *Cyclopædia of India*.) Castor oil seeds are planted in July in the Districts of North and South Arcot, Salem and Coimbatore, the crop is gathered in February—the seeds are sown only on the poorest description of dry land, whose assessment is from 1½ to 3 Rupees per cawny.

Many varieties of *Ricinus* grow wild in Bengal, upper India, Malabar, Canara and Guzerat (*vide Cyclopædia of India, para. 2,457—5,740—7,165 and particularly page 1607 and following*) all these plants produce seeds containing an oil appropriate for the manufacture of vegetable wax.

The land for castor oil seeds receives five ploughings, deep furrows are then traced on the field with a plough, and a man deposits one or two seeds every three and sometimes every two feet, into the furrows and covers the seed with earth by a slight motion of his foot, the furrows are about three feet apart, sometimes more—when the castor oil seeds are planted in that way, the whole field is sown broad cast with one of the three following seeds—1st Thowaray (*Cajanus indicus*) 2nd Ooloondoo (*phaseolus mungo*) 3rd Caramany a plant of the leguminosæ family (see *Cyclopædia of India, para. 2,508*) the average produce of one cawny of that description of land, planted in oil seeds and small grains is 1,000 lbs. of oil seeds and an equal quantity of the small grain—the castor oil seeds and small grain generally fetch the same price in the market of Vellore, viz., 14 to 16 seers per Rupee, when the soil is richer, the produce is sometimes as much as 2,500 and 3,000 pounds of *Ricinus* seeds per cawny—to show to what use may be brought the large tracts of waste land found in the Carnatic, only the poorest description of land, will be considered. Herewith is given an accurate statement of the expense of cultivation and produce of dry land assessed near Vellore at 2 Rupees per cawny : and having had during two years, large plantations in that district, Mr. Loarer vouched for the accuracy of his statements.

Cost of cultivation of one cawny of dry land

Harvesting and packing....	2	8	Same observations as above.
Manufacture of the seeds into oil.. .... .	5	0	
Carriage to Madras ....	2	0	
Total cost Rupees....	19	6	

Produce and sale of the above, a measure weighing about 4 pounds.

250 measures of oil seeds at 1 Anna each .. .. .	15	10
250 do of Thowaray 1 Anna each... .. .	15	10
Stalks and straw.. .. .	2	0
Total produce Rupees...	33	4

There is brought to account all the expenses for ploughing, sowing, harvesting, manufacturing and packing the crop, at a very remunerative price for the ryot (for such were the prices paid when employing villagers at Lattery near Vellore) the net profit of the ryot will be 14 Rupees per cawny, after having been paid for all his works. *Note.—When oil seeds sell for one Anna a measure it is a very remunerative price, oil then sells at 40 Rupees per candy:*

In obtaining castor oil good sound seeds yield from 43 to 45 per cent of dark lamp oil, by the boiling and roasting process; oil prepared by that process is very thick, black and viscid, and is preferred for the manufacture of vegetable wax as the albumen in the seeds has been destroyed by the roasting process. Oil of a better colour and more fluid is prepared by boiling the seeds, then peeling them and afterwards passing the almond to the mill but the yield is only from 36 to 40 per cent.

Lastly a limpid and perfectly fluid oil known as *cold drawn castor oil* is obtained for medicinal purposes and sold by Apothecaries, the produce of a hundred pounds of seeds in *cold drawn castor oil*, is very seldom above thirty-three pounds per cent.

(For very complete details of the history, natural and commercial, of the oil seeds in general and castor oil seeds in particular and on the manufacture and prices of that oil—See Cyclopædia of India, page 311 and seq. page 1326 & seq.)

The chances of a tolerable crop in barren land such as is assessed at  $2\frac{1}{2}$  Rupees per cawny is two good years and a bad one—great rains are most dangerous to the plant as soon as it begins

## WAX, VEGETABLE.

to flower—the plant flowers during the end of September and all October, these two months are very critical for the prospect of the crop. The castor oil plant withstood very well the terrible droughts of 1854 and 1855, the crops of these two years were average ones—the great rains of September and October 1857 destroyed the whole plantations of that year, and the price of lamp oil rose from 40 Rupees in October 1857, to 55 Rupees as it stands now.

With oil selling steadily at 45 Rupees per candy, the culture of the castor oil plant is very remunerative, and if a Ryot be sure of always selling his oil seeds at one Anna per seer he would till thousands of cawnies now left barren. If further the Ryot had certain means of disposing of that part of his crop without passing through the claws of half a dozen Vaniahs, he would very soon better his condition and in the meantime contribute an unexpected source of revenue to the State, for it is necessary to understand, that not one inch of the land now under cultivation for cereals, should be given to the cultivation of oil seeds, the Ryot would resort for this supplement to his income, to tracks of land never cultivated before, and Government knows there is no lack of waste lands—One of the best means for enhancing the abundant production of castor oil seeds would be the establishment of central work shops where the seeds could be converted into oil and vegetable wax for the Ryot himself, on payment of a small per centage.

In the manufacture of the vegetable wax the manufacturer, as will now be shown can very well afford to pay 45 Rupees per candy of oil, and it is also cheaper to convert oil into vegetable wax for shipment, than to send to Europe the oil in casks.

Cost of ten tons of vegetable wax at the Custom House, Madras:—

25,000 lbs of coarse lamp oil at 45 Rupees per candy...	2,250	0
Cost of reducing the same into vegetable wax... ..	25	0

Total cost in London... X + 3,633 12

'X' will always be heavier than X but we can afford to put them as equal and eliminate them, we will have then the following results.

2,720 for vegetable wax.

3,630 for lamp oil.

But oil is subject to a considerable leakage, and the minimum reckoned upon is 20 per cent ;

## WAX, VEGETABLE.

we must then add 20 per cent to the price of lamp oil and we will have then

Price of 25,000 lbs. of vegetable wax in London, .....	Rs. 2,720
Price of 25,000 lbs. of lamp oil in London, .....	4,356

Difference for vegetable wax... 1,636

The means is known for re-converting vegetable wax into lamp oil by a very simple and economical process.

The price of coarse castor oil in London varies from 4½ to 6 pence per pound according to demand—vide *London Public Ledger*, the most complete commercial advertiser.

The price of vegetable wax, though completely new in the market, has never been under £38 per ton; it sold at Havre on the 25th of June 1858 at 51 and 52 Francs per 50 kilogrammes.

The duty on that produce is fixed in France at 50 centimes (5 pence) per hundred pounds; in England it enters duty free; vide *London Public Ledger* of the 25th January 1858, art. wax, public sales. 516 Baskets Madras vegetable wax, were bought in at 40 Shillings.

Same journal 2nd page, 1351 baskets of Madras vegetable wax per "*Triumph*" to be sold on Friday 29th January 1858 at the Baltic sale rooms.

The cheapness of the vegetable wax may be illustrated by mentioning that the horse grease a horrid compound, the product of ebullition of the unhappy omnibus and hackhorses of London and Paris, a black, soft, fetid grease, never sells in London or Paris under £32 per ton, should vegetable wax never reach a high level in the markets of England and France, it would yet afford a very ample remuneration to the manufacturer, and it must be borne in mind that it is altogether a new produce, a new culture, and that the revenue, the ryot, the carrier, the Custom House, the boatman, the sailor, have already had an ample share in the benefits offered by this new branch of commerce.

### Process for re-converting vegetable wax into oil.

The vegetable wax should be melted with water at a gentle heat, (not to make it boil); when the wax is melted it must be drawn from above the water by a syphon or a cock and put into a large vat, at the bottom of which there is a layer of bisulphate of potash swimming in a sufficient quantity of sulphuric acid, so as to prevent the oil coming in contact with the bisulphate of potash.

The room where the vat is, must be kept for 24 hours at a heat of 140° by means of a stove, the heat should be then gradually decreased to 120° and 100° and in four days the oil will be perfectly liquid and will congeal no more.

In Extract from the Minutes of Consultation, in the Public Department, dated 13th October 1858, No. 1271. The Right Hono-

## WAX, VEGETABLE.

able the Governor of Madras in Council remarked that the report submitted by the Committee is very favorable to Mr. Loarer's proposition, and furnishes a comparative calculation of the cost of manufacturing the Vegetable Wax, from which it appears that Mr. Loarer's process is of a far more economical nature than that described in Chemical Books. By the experiments by Mr. Norton, the cost for one ton is Rupees 112-1-6; while by Mr. Loarer's process No. 1, it is Rupees 4-4, and by process No. 2, only Rupees 1-11-3 per ton. The Government observed that the value of the discovery depends on its really proving the means of increasing the export of one of the commonest articles of indigenous produce which at present does not find its way into foreign markets on account of the form in which it is prepared, not enabling it to bear the cost of transport. The demand for Wax and Stearine in Europe is so large and so permanent, that the Governor in Council has no doubt this Vegetable Wax will command an extensive sale.

The Governor in Council authorised the sum of five thousand Rupees for Mr. Loarer, and guarantee a further payment of five thousand Rs. to Mr. Loarer on the export of 500 tons of the Vegetable Wax.—*Madras Committee's Report on Mr. Loarer's Vegetable Wax.*

More recently, Mr. Loarer experimented on samples of the following oils, viz.;

a. Illipoo.	f. Cotton seed.	k. Croton tiglium.
b. Margosa.	g. Mustard.	l. Ground nut.
c. Piney cotay.	h. Rape.	m. Cold drawn castor.
d. Cottomanaka.	i. Ramtil.	n. Coconut.
e. Wood.	j. Soapnut.	o. Gingely.

All the samples apparently were genuine, unadulterated and of good quality. He subjected each oil to the usual Chemical treatment for the manufacture of Vegetable Wax and the following were the results.

(2997) *Illipoo Oil*, produces with great facility a perfectly white substance of the consistency of good tallow, Illipoo oil is with great advantage mixed with Castor oil for the manufacture of Vegetable Wax, and as Illipoo oil has always fetched a very low price in the Madras Presidency, the discovery of this property renders it very valuable and will enhance its price for the future.

(2998) *b. Margosa Oil*, produces a vegetable wax as hard as any made from the best lamp oil and of a light saffron color. Margosa oil has always been sold in the Madras Presidency at a very low price but its supply has never reached what it could attain should this oil become saleable. Margosa as well as Illipoo oil mixed with an equal quantity of cold drawn Castor oil produces a hard vegetable wax of an agreeable roseate color.

(2999) *c. Pinnacotay*, produces a thick jelly of a dark olive color and by the addition of a small quantity of sulphuric acid the jelly as-

## WAX, VEGETABLE.

sumes a dirty orange color and swells into a soft, elastic substance of the appearance of sponge cake.

(3000) *d. Cottamanaka Oil*, is changed by Mr. Loarer's process into a thick jelly of a rich saffron color, but never hardens. A small quantity of Sulphuric acid causes the above jelly to swell to nearly double its original volume, but the *Magma* never thickens.

(3001) *e. Wood Oil*, is decomposed by Nitric acid into a black spongy substance, hard and brittle, heavier than the liquid part of the oil into which it sinks: the liquid part assumes a color nearly like that of Port Wine and is about as fluid as water, much more liquid than the natural Wood oil. A thin coating of that liquid part applied to a board of deal wood formed in twenty four hours a transparent varnish perfectly even and bright, the spongy matter above alluded to seems to possess the same properties as a mixture of rosin and Anotto. He obtained two identical substances by dissolving with Nitric acid, the common asphalte used for pavements. A small quantity of Sulphuric acid poured uncautiously on the second day into the Wood oil which had been in contact with Nitric acid caused it to rush out of the glass with a violent effervescence and disengagement of smoke aromatic fumes and a heat of about 200° Fah. the aromatic smell was very sweet and much like Benjamin. He thinks the Wood oil worthy of great attention on account of the varnishes it can supply.

(3002) *f. Cotton Seed Oil*, was insensible to the treatment by nitric acid and after 48 hours remained as clear as when poured out of the bottle a few drops of the sulphuric acid mixed to the oil after the 48 hours of contact with nitric acid caused a violent eruption and all the phenomena recorded for Wood oil the only difference being for Cotton oil the absence of the aromatic fumes.

(3003) *g. Mustard Oil*, remained unchanged under action of nitric acid alone. A few drops of sulphuric acid caused the oil to assume a reddish muddy color and on the fifth day decomposed into a light spongy matter having a viscid appearance floating upon a red limpid oil.

(3004) *h. Rape Oil*, has undergone identical changes to what is recorded of Mustard oil.

(3005) *i. Ramtil Oil*, same effects and results as per Mustard and Rape oil.

(3006) *j. Soapnut Oil*, same effects as above.

(3007) *k. Croton tiglium*, unchanged by Nitric acid: the addition of a small quantity of sulphuric acid caused, in 48 hours, a decomposition of the oil, the sides of the glass became coated with a soft elastic crust of a pale dirty yellow color and very similar in its velvet like appearance to lees of freshly made wines or of the fungus on vinegar.

## WEIGHTS AND MEASURES.

(3008) *l. Ground nut Oil*, unchanged by Nitric acid and the addition of sulphuric acid causes the oil to assume a dirty and muddy red color, but the limpidity is not changed.

(3009) *m. Cold drawn Castor Oil*, becomes red and soon solidifies into a dirty pale yellow mass.

(3010) *n. Coconut Oil*, unchanged by three days of contact with Nitric acid, on the fourth day added a proportional quantity of sulphuric acid and noticed no change on the fifth and sixth days, the change if any being an additional fluidity of the oil but from a dirty white the oil has become pale red.

(3011) *o. Gingely Oil*, conducts itself with the two acids exactly like Coconut oil.

Mr. Loarer thinks that the Mustard, Rape, Ramtil, and Soapnut oils would become eminently siccative after undergoing a careful treatment of Nitric and Sulphuric acids and could be used for paints in supercession of Linseed and other similar oils.—*Mr. Loarer's M.S. Report to Madras Committee reporting on the Resources of India.*

## (3012) WEIGHTS AND MEASURES OF INDIA AND SOUTHERN ASIA.

*General remarks.* With the exception of the weight of the Rupee, (180 grains), there exists no defined standard of Weight or Measure in India. There are certain traditional standards, but these differ all over the country, and in practice are not adhered to, nor is there any Law on the subject, by which the gross irregularities that prevail can be checked.

The unit of *Linear* measure in India, is generally the distance from the elbow to the tip of the middle finger of a tall man. This length is known as the *hat*, Hind., or *moolum*, Tam, *mora*, Tel., and averages  $19\frac{1}{2}$  inches. It is always translated *cubit*, though invariably exceeding the English cubit of 18 inches, by  $1\frac{1}{2}$  or 2 inches. In the Southern Carnatic, the *adee*, or length of a tall man's foot, is in use, and averages  $10\frac{1}{4}$  inches. The *Guz* of India, (translated *yard*), is partially in use all over India, but varies in different localities from 26 to 36 inches. In Bombay it is 27 inches, and in the North-West Provinces of India it has been defined by Government, for the purpose of Survey, at 33 inches.

Although the above are the *Indian* linear measures, the English yard and foot are very extensively adopted by Native artizans; and in all the Public Works of India, which give employment to thousands of Natives, the English linear measure is invariably employed. Considering therefore that this Measure is already so familiar to the people, and that their own is so undefined, and fluctuating in practice, there can be little doubt but that the English Yard and Foot should be determined on as the new Metrical system.

## WEIGHTS AND MEASURES.

*Superficial* measure need only be noticed in connection with *Land measure*. According to the ancient Indian practice an area of land is often named after the quantity of seed required to sow it, or the quantity it will produce, and of course the actual area differs according to the opinion of the person who makes the estimate. Where linear definition is given, mention is made of Rods or Ropes, of so many cubits, but the cubit is undefined, and areas of the same denomination, are derived from different multiples of the Rod or Rope. Of the more definite terms the *Bheega* prevails in Bengal and the North-West Provinces. In Bengal it is 1,600 square yards, and in the North-West Provinces it is 3,025 square yards. In the Bombay Presidency it is not authoritatively defined, but averages about  $\frac{2}{3}$  of an acre. The term is quite unknown in the Madras Presidency, where the authorised measure is the *Cawnie* of 57,600 square feet, or 1.3223 acre; there are also other local land measures defined, but presenting great differences one from the other; as the *chain* of 3.64 acres, the *seed-cottah* of 1.62 acres, the *vaylie* of 6.6 acres, and the *bullah* of 3.82 acres.

The greater portion of the North-West Provinces of India has been surveyed by Government Officers. The area of each village (or rather parish, to use an English term) is given in Imperial acres, but the areas of the *fields* appertaining to each village, are given in local *bheegas*. The introduction of the acre therefore was only partial. In the Surveys lately made in the Bombay Presidency, the area of each field is recorded in acres, not only in the English, but in the vernacular accounts, and the term is well known and understood among the people. In the Madras Presidency, the districts of Bellary and Cuddapah were measured field by field (as far as the land was cultivable) in acres, in 1803, and Kurnool in the same way in 1842. In Salem, the records of field measurements made about 1800, are entered both in the Native terms and their equivalents in acres, and the acre is by far the best known.

Under the above circumstances, the introduction of the Imperial acre seems not only most desirable, but quite feasible. Where lands have already been *accurately* measured, and contents recorded in Native terms, those terms might be converted into acres; and in the progress of the Surveys now going on, all measurements might be at once in acres. This plan has already been successfully adopted in the present re-survey of the Southern districts of Madras, and the acre is superseding the *cawnie*. In the new survey now in progress in the Madras Presidency, acres and hundredths of acres are employed.

With regard to the *subdivisions* of the acre they have hitherto in the Madras Presidency been in 40ths (or Goontas), and 16ths of 40ths; or else in 16ths (annas) and 4ths of 16ths.

## WEIGHTS AND MEASURES.

Where the natural fractions of halves and quarters, are not employed, a decimal subdivision is most desirable; not only is the computation far easier to the surveyors, but records in decimals, are far more intelligible than in Roods and Perches, and money values in relation to areas more easily calculated. The areas recorded in the Ordnance Survey of Great Britain, in which Survey every field is measured, are now in acres, and *decimals* to the third place. There cannot be a better authority for a decimal subdivision, and it offers no difficulty to the Natives, as regards *land* measurement. It is hardly necessary to argue why a decimal subdivision of *Land* measure, should be easier of introduction than a decimal arrangement of Weights and Measures in general. It is, in practice, a mere division of account. In England not one person in a thousand is the least put out by the substitution of Decimals for Roods and Perches: whereas, not one in a thousand but would be inconvenienced (for a time) by the substitution of 10ths of Gallons for Pints, or by Ounces of ten to the Pound. The *cawnie*, itself, is in several districts in the Madras Presidency, subdivided into 100ths, and in the present re-survey of the Southern Districts of Madras, the decimal subdivision of the acre has been authorised, as stated above.

The larger Weights throughout India are utterly devoid (in practice) of rule or uniformity, being generally misshapen lumps of metal, or stones, and varying in value as well as denomination in every district almost. The traditional and acknowledged unit of Weight is generally the RUPEE; thus the "Seer" is said to be so many Rupees weight; but it is very seldom possible to say what was the weight of the Rupee forming the original unit. The Rupees of the different Native Governments varied considerably, and even under the British rule the Sicca Rupee of Bengal was 192 grains, when the Arcot Rupee of Madras was  $176\frac{1}{2}$ . These differences in the small unit would effect the larger ones considerably, and aggravate the uncertainty as to what was their original and real value. Besides this, terms of the same denomination do not by any means denote the same value. A Candy, (Khundee) for instance, in one place differs very much from the Candy of another place. Again, a Candy, for instance, of Metal, is not the same as a Candy of Tobacco; and there is a different Candy for Cotton and Sugar. The Candy used in buying, is not always the same in the same place, as the Candy used in selling. There has however, from time immemorial been a small weight called a *tola*, in use by Goldsmiths and Jewellers, which has maintained a ponderary value of about 182 or 184 grains. The Furruckabad rupee used in the N. W. Provinces, had hitherto been 180.234 grains. The Rupee of Madras and Bombay had been for some years

## WEIGHTS AND MEASURES.

180 grains. The "Sicca" Rupee of Bengal still remained at 192 grains, but this coinage was discontinued in consequence of Act XVII. of 1835, and since that date the Company's Rupee of 180 grains has been the only Rupee coined at any of the Government Mints. When the Government of India, by Act VII. of 1833, (the main purport of which was to fix the weight of the Furruckabad rupee at 180 grains) decided on 180 grains as the *tola*, they in the same Act declared that this *tola* should be "the unit of a general system of *Weights* in all Government transactions."

The "Table" of Weights adopted by the Government of India for the use of their own offices, is in accordance with Native usage in Bengal, and was approved of by the Chambers of Commerce in Calcutta and Bombay. It is as follows:

1 Tola	=	180 Grains.	
5 Tolas	=	1 Chittak.	
16 Chittaks	=	1 Seer = 80 Tolas	= 2.057143 lbs. avoird.
40 Seers	=	1 Mun = (or maund) =	82½ lbs. exactly.

If any system of Weights be selected from those now current in any part of India, the above seems to be the best, not only because it is founded on a defined standard, originating in the weight of the coin of the realm, but because it includes the "Seer" of 80 tolas, which is a weight known and acknowledged in *some* degree all over India. It is in short a Ponderary system which as far as *facility of introduction* is concerned, has a preference over any other.

In the 140,000 square miles comprised in the Madras Presidency, not a single bazar-man has altered his Weights one grain, or his Measures one fraction of a cubic inch in consequence of the Calcutta notification. Neither was the Act intended to go farther than legalise the *tola* as a unit. The "Table of Weights" has never been adopted in the Madras Presidency, even in *Government transactions*. In the Fort St. George Gazette of the 20th October, 1846, the following Table of Weights was published as that which was to be used in that Presidency:

180 Grains	=	1 Tola	
3 Tolas	=	1 Pollum.	
40 Pollums	=	1 Viss = 120 Tolas	= 3.0857 lbs avoird.
3 Viss	=	1 Maund = 960 Tolas	= 24.6857 lbs avoird.

This "Table" was sanctioned for Madras by the Government of India, and is, as will be seen on comparison, entirely different, with the exception of the *tola* unit, from the Weights adopted for Calcutta.

It will be observed that the Madras Government Table does not acknowledge the "seer" weight at all; but still a seer weight of 80 tolas, known as the "pucka" seer is met with all over India. This quantity is not much in use in Southern India, where the "seer" of 24 tolas, called the "cutcha" seer, is more common. The original unit of WEIGHT in Southern India, seems to have been the gold coin called by the English,

## WEIGHTS AND MEASURES.

a "pagoda." It is now uncurrent, but was about 52½ grains weight. 80 pagodas weight is, according to the Native Tables, a "seer" (cutcha) of 24 RUPEES weight. This corresponded with the average weight of the old Native rupees of 175 grains; but since the introduction of the "Company's rupee" of 180 grains, the "pagoda weight" is 54 grains generally. The same confusion formerly existed in Bengal, between a Sicca WEIGHT of 179½ grains, and a Sicca RUPEE of 192 grains. There are also "seers," both in Madras and Bombay, of 84 Rupees weight. Still, a seer of 80 tolas could no doubt be more easily introduced throughout India than any other weight.

The Calcutta official "man" or maund, is 82½ lbs, avoirdupois, and is not known in any part of the Madras Presidency, except at the Government Salt Depôts, and in the Coast trade of grain to the port of Madras. The Madras maund is 25 lbs; the Bombay maund is 28 lbs.; and the Surat maund in use on the Western Coast is 31½ lbs.

The chief objection to the Ponderary system enunciated by the Government of India, is that it cannot be made to accommodate itself to the Imperial Weights of Great Britain, and this, considering the importance of the trade between the two Countries, and the fact that one is a Dependency on the other, is a serious drawback.

The following Table shows the nearest proportions that can be obtained, for converting the above system of Weights, to those of Great Britain (avoirdupois).

38,889 Tolas	= 1 lb.
350 Tolas	= 9 lbs, <i>exactly</i> .
1 Seer	= 2.057143 lbs
35 Seers	= 72 lbs. <i>exactly</i>
1 Mun	= 82½ lbs. <i>exactly</i> : or (82 2857143.)
7 Muns	= 576 lbs. <i>exactly</i>
49 Muns	= 36 cwt. (of 112 lbs.) <i>exactly</i> .
27,216 Muns	= 1 ton (of 2240 lbs)
490 Muns	= 18 tons <i>exactly</i>
300 Muns	= 11 tons (strictly 11.0204)

It will be seen that under such a system, there will always be difficulty and confusion in adjusting the weights of articles of commerce to the English Table, and as the connection between the two countries increases, and the European element becomes more marked, the inconvenience will be more practically felt.

Mr. Prinsep, in his "Useful Tables" gives a list of some 300 Rupees of Native Mints, mostly of dates prior to any regular coinage of the Indian Government. They average about 175 grains; and had the Government adopted 175 grains instead of 180 for the rupee, a "Seer" of 80 rupees would have been exactly 2 lbs. avoirdupois; and a "Mun" of 40 seers, exactly 80 lbs. avoirdupois, and 25 Muns exactly 2,000 lbs., or the proposed new Ton for Great Britain. The rupee of 180 grains is now so well established in all the Presidencies, and there is such an enormous silver circulation in India, that it seems impracticable to reduce the Rupee to 175 grains; and if the same content of pure silver were re-

## WEIGHTS AND MEASURES.

tained, (which would be necessary for the credit of the State) the "touch" would be raised from ½ or .91666, to .942, which may be deemed too high for durability. The touch of silver in France (where, as in India, it is the legal standard of value) is .900. In England it is .925.

Mr. Bayley proposes a "seer" of 77½ tolas, instead of 80. As far as the facility for testing doubtful weights by the coin of the country, this would answer as well as 80 tolas, for a quarter rupee is just as much a coin of defined weight (45 grains,) as a whole rupee, and where one can be obtained, the other can.

This "seer" would differ 2½ tolas weight from the one adopted for Government transactions in Calcutta, but practically the "seer" Weights in India, even though professing to be 80 tolas weight, are seldom so much. The seer is generally said to be so many rupees weight, and as the rupees of former days, on which these seers were founded, averaged about 175 grains, the original weight would be more nearly obtained by a "seer" of 77½ tolas. Besides, as has already been stated the 80 tola "seer" is not universal the "seer" weight varying in different localities, and to substitute a 77½ tola weight in these localities, would not be more of an innovation, than substituting a "seer" of eighty tolas.

The "seer" of 77½ tolas would be only 5 grains short of a double pound, or two pounds avoirdupois; that is, it would be 13995 grains, instead of 14000; which would only make a difference of 1.42 lbs in a proposed new Ton of 2000 lbs, a difference within the limits of error in weighing. It would be advisable perhaps, to define the "seer" legally, as equivalent to two avoirdupois pounds; and it might at the same time be declared that a seer of 77½ tolas weight would not be condemned as short.

It will be observed from what has been stated above, that the Government of India has neither in Act VII. of 1833, nor in the "Table" set forth by them, made any allusion to Measures of Capacity, although it is a matter of more importance than the Weights, seeing that by far the greater portion of the domestic transactions in India are in grain. The Calcutta Chamber of Commerce, when on the 19th of May, 1836, they resolved to adopt the Weights of the Government, urged the introduction of the Imperial gallon for Liquids, and proposed that new Measures of capacity for grain, should be regulated by the Weights, but they did not show how this was to be done; nor does it seem at all necessary to make a distinction between "Dry" and "Liquid" Measures. The Government declined to act on the recommendation of the Chamber, and whatever might have been contemplated by Act VII. of 1833, nothing has ever been announced by way of defining the capacities of the Grain Measures in Bengal. The only Measures made up (at the Mint) by authority of the Go-

## WEIGHTS AND MEASURES.

verment, are the Imperial gallon and its sub-multiples, for use in the Medical and Victualling departments; and it seems that the Court of Directors in their Despatch of 17th July, 1833, expected the "general adoption in India" of the Imperial Measures. The *Madras* Government however in their Notification referred to above, promulgated a Table of Measures to be used in Government transactions, as follows:

1 Olluck =  $12\frac{1}{2}$  cubic inches.  
8 Ollucks = 1 Measure (Puddee) = 100 cubic inches.  
8 Measures = 1 Marcal = 800 cubic inches.

And this arrangement was sanctioned by the Supreme Government for the Madras Presidency. Though 10 years have elapsed, these Measures have not been adopted by the people; and even in the Town of Madras, the Government have authorised the stamping with the Government Seal, the "customary" Measure or "Puddee" of  $104\frac{1}{4}$  cubic inches, which has been the *real* standard since 1802.

In Bombay, the Government have attempted to introduce a "Seer-measure" of the capacity of 57 cubic inches, but this being so much smaller than the usual "Seer-measure" of that Presidency, the scheme has not met with success.

Mr. James Prinsep's observation that "India does not, properly speaking, possess Dry or Liquid Measures, and that where these are employed, they depend upon, and in fact represent, the "seer" or "maund" weight," is true of India generally, but in the neighbourhood of Madras and in some of the Southern Districts, the ordinary grain Measure is a "puddee," which does not represent any weight; and the "puddee" varies greatly in different localities.

The most common grain Measure, and one which is to some extent known in almost every part of India, is the "seer-measure;" this is always understood to be a Measure which *when heaped* will contain a "seer" weight of rice, or in some places instead of rice, a mixture of the 9 most common grains, known as the *nou-danium* measurement. The 9 grains used in the Madras Presidency, are Rice, Chenna, Cooltee, Pes-soloo, Minamaloo, Dholl, Anamaloo, Gingely oil-seed, and Wheat. As only *heaped* measure is recognised by Native usage, it is evident that there is no rule as to the *cubic content* of the Measures used; for vessels of very different cubic content may contain the same when heaped, in consequence of having different diameters. It is on this account that the values given to Indian Measures, in such Tables as those of Major Jervis, or Dr. Kelly (in his *Cambist*) being founded on the gauged cubic contents, do not represent the true quantities.

In 1852, the Madras Board of Revenue instituted a special enquiry into the Grain Measures of each district. They were found to be of all shapes and materials. Some were in the form

## WEIGHTS AND MEASURES.

of hour glasses; some were joints of bamboo, and some earthenware pots; but as a general rule, it was found that they were in most districts intended when *heaped*, to contain a seer weight, or a definite number of seers, either of rice, or of mixed grain, but usually rice; and the "seer" weight was generally that of 80 tolas. Measures in every district were gauged with Water, Rice, and Cooltee or Horse gram, and it was found that (taking 100 cubic inches of water to weigh 140 tolas, which at a temperature of  $81^{\circ}$  is true to  $\frac{1}{2}$  a grain) Rice on an average, weighed 113 tolas to the 100 cubic inches. In the Northern Districts, it averaged 111 tolas; in the Town of Madras 114 and in the other Districts 112 and 113. The rice used was what is called in Madras, "Putcharisee, TAM.," Kucha Chawul, HIND., or RAW RICE, to distinguish it from "Poolungul, TAM.," Oobala Chawul, HIND., or that which is scalded before husking. Old rice would weigh something lighter. From experiments made by Mr. Bayley a few years ago, he found 100 cubic inches, of the 9 mixed grains, to weigh 115 tolas. From the Reports of Mr. Shaw, of Ahmedabad, in the Bombay Presidency, in 1849, it appears he found that a Measure holding  $137\frac{1}{4}$  tolas of water, held when struck  $114\frac{1}{4}$  tolas of mixed grain, which gives  $116\frac{1}{2}$  to 100 cubic inches; and Mr. Reeves, of Poona, found that a vessel containing 80 tolas weight of water, would hold  $66\frac{3}{4}$  tolas of mixed grain, which also gives  $116\frac{1}{2}$  tolas to 100 cubic inches. Cooltee, or Horse gram, was found by the Madras experiments to average 116 tolas to 100 cubic inches, but it varied from 113 to 118. From the same experiments, the weights of the *heaps* (of rice) on various diameters were determined, as shown in the margin; but it is probable that the dealers in the bazaar, would not heap quite so liberally. The accuracy is of course not so great but that the diameter may be considered either the inner or outer.

The best "Seer-measures" are about  $3\frac{1}{2}$  to  $3\frac{3}{4}$  inches in diameter, and 6 inches deep, but they are never true cylinders. Their cubic contents are from 66 to  $66\frac{1}{2}$  cubic inches, holding from 74 to 75 tolas of rice when *struck*, and 80 when heaped. It so happens that a vessel of  $66\frac{1}{10}$  cubic inches capacity will contain at a temperature of  $84^{\circ}$  (a good day temperature for India,) 16650 grains, or *exactly*  $92\frac{1}{2}$  tolas weight of water. This would hold on an average when *struck*,  $74\frac{1}{4}$  tolas weight of rice; and with a diameter

74 tolas weight of rice; and with a diameter

## WEIGHTS AND MEASURES.

of 3.7 inches, 80 tolas if *heaped*. Thus if a "seer" of 80 tolas be adopted, such a Measure would be exactly what is understood by the Natives of the country to be a "Seer-measure."

The sub-multiples of the "Seer-measure" are generally (not always) used for *Liquid* measures in India. The only liquids sold by measure, are Ghee, (clarified butter,) Oil, and Milk. No defined measure is used for Arrack and Toddy (intoxicating liquors), and Spirits in Madras are sold by the "dram" of 5.775 cubic inches, or  $\frac{1}{160}$ th of the old Wine gallon.

Instead of making 40 "seer-measures" = 1 "Mun-measure," which might cause a confusion in the terms of Weight and Measure, (and the term Mun or Maund is not in use as a grain measure in Southern India,) it would be better to give some name to a quantity represented by 100 Seers. This might be called a "Saotee," from *sao*, a hundred. The "Table" adverted to above would be as follows :

DRY AND LIQUID MEASURES.							
Seers.	Cubic inches.	Tolas of Water.	Tolas of Rice when struck.	Tolas of Rice in heap.	Total weight	Diameter inches	Depth inches
I.	61.1	92 $\frac{1}{2}$	74 $\frac{1}{2}$	51 $\frac{1}{2}$	80	3.7	6.2
II.	123.2	185	149	11	160	4.5	7.7
III.	198.3	277 $\frac{1}{2}$	223 $\frac{1}{2}$	16 $\frac{1}{2}$	240	5.3	9.0
IV.	264.4	370	298	22	320	5.7	10.3
V.	330.5	462 $\frac{1}{2}$	372 $\frac{1}{2}$	27 $\frac{1}{2}$	400	6.2	10.9
VIII.	528.8	740	596	44	640	7.3	12.8
X.	661.0	925	746	55	800	7.7	13.0
LIQUID MEASURE.							
$\frac{1}{2}$	33.0	46 $\frac{1}{4}$				3.0	4.7
$\frac{1}{4}$	16.5	23 $\frac{1}{8}$				2.5	3.4
$\frac{1}{8}$	8.25	11 $\frac{1}{16}$				2.0	2.6

Mr. Bayley proposes as a Measure of *Capacity*, a vessel to be called a "Seer," but exactly equivalent to an Imperial Quart. The present "seer-measure" averages a capacity of 66 $\frac{1}{2}$  cubic inches: the Quart is 69.3185. The present "seer-measure" contains when *struck*, about 74 tolas of rice, or 76 of mixed grain, and about 80 tolas of either when *heaped*: the Quart would contain 78 tolas of Rice, or 80 of mixed grain when *struck*, and (with a diameter of 4 inches,) about 86 tolas when *heaped*; but *heaped* measure should not be recognised by Government. He thinks that as there exists an English Measure which corresponds (taking *struck* content) so closely to the Native "seer" of 80 tolas, or to the "seer" of 77 $\frac{1}{2}$  tolas which he has proposed, that it should be adopted, which ever of the two "seers" of *weight* the Government may select. It is also to be added, that the Quart will contain an even number of tolas (rupees) weight in water; namely, 17450 grains,

## WEIGHTS AND MEASURES.

or 97 tolas *exactly*, at a temperature of 84° Fahrenheit. This may be calculated from the former Table.

The "Seer-measure" then, would be defined as a vessel containing 97 tolas of water at a temperature of 84°, and its bulk 69.3185 cubic inches. A reference to the water being *distilled*, or the height of the Barometer, will not be necessary in practice. The Barometer in the Tropics fluctuates very slightly, and a fall of 1 inch, due to an elevation of about 940 feet, would only make a difference of .615 grain, to be deducted from the normal 97 tolas assigned to the Quart-seer.

It would not be necessary, if the Government recognized *struck* measure only, to define the diameters (or even the shapes) of the vessels of capacity, for all that is required is that they shall contain a certain number of tolas weight of water. Still for uniformity's sake, and the more easy discovery of fraud, the vessels should be cylindrical, and it would be desirable that the models, as well as all vessels made up at the Government Stores, should have a diameter proportionate in some simple ratio, to the depth. The diameter the same as the depth would be the best, but those who are accustomed to measuring grain and salt, assert that this would be too broad to be convenient, and a diameter one half the depth too narrow. A good proportion is that of 3 to 4, and the contents of a cylinder being given, it is easy to compute the requisite diameter and depth

Let  $s$  = cubic contents given.

$d$  = diameter to be found.

$h$  = depth to be found.

3:4 = diameter to depth.

$$\text{Then [I] } d = 3 \sqrt[3]{\frac{s}{.7854 \times \frac{4}{3}}} = 3 \sqrt[3]{\frac{s}{1.0472}}$$

$$\text{And [II] } h = \frac{s}{d^2 \times .7854}$$

From these Formulæ, we obtain the following Table for both *Dry* and *Liquid* Measure.

Quarts.	Tolas water at 84°	Cubic inches.	Diameter in inches.	Depth in inches.	Tolas Rice. 113 tolas to 100 cub. in.
I.	97	69.3185	4.04	5.39	78.3
II.	194	138.6370	5.10	6.80	156.6
III.	291	207.9555	5.83	7.80	234.9
IV.	388	277.2740	6.42	8.57	313.2
V.	485	346.5925	6.92	9.28	391.5
VIII.	776	554.5480	8.09	10.79	626.4
X.	970	693.1850	8.71	11.62	783.0
$\frac{1}{2}$	48 $\frac{1}{2}$	34.66	3.18	4.25	39.2
$\frac{1}{4}$	24 $\frac{1}{4}$	17.33	2.55	3.40	19.6
$\frac{1}{8}$	12 $\frac{1}{8}$	8.66	2.00	2.68	9.8

## WEIGHTS AND MEASURES.

If a "Seer" Weight of  $77\frac{3}{4}$  Tolas = 21lbs Avoirdupois, were adopted, the "Seer-measure" if the vessel be struck, would correspond sufficiently; for the weight of rice varies from 112 to 114 tolas to 100 cubic inches; and if the 9 grain standard be taken, the above "Seer-measure" will contain just 80 tolas (at 116 tolas to 100 cubic inches) and be when *struck*, the exact equivalent of what is now the average "Seer-measure" when *heaped*. This of course will render its introduction much easier than any other struck Measure that can be adopted.

Even in the Madras Presidency, where the "Seer-measure" is not recognised in the Government Notification, such a Measure averaging 80 tolas weight of Rice when *heaped*, is in use in many of the Districts, and the Sepoys of the Native army always buy by the Seer, generally considering it to be  $\frac{2}{3}$  of the Madras "Customary" Measure of  $104\frac{1}{4}$  cubic inches, which would give  $69\frac{1}{2}$  cubic inches, or an Imperial Quart. On the 17th July, 1855, the Madras Government, in consequence of some dispute on the subject, decided that the Sepoys' "Seer-measure" should be  $5\frac{1}{2}$  of the "Ollucks" named in their proclamation of 1836, or  $68\frac{3}{4}$  cubic inches. This closely corresponds with the Quart of  $69\frac{1}{2}$  cubic inches, which Mr. Bayley proposes as the standard "Seer-measure."

The only multiple of the "Seer-measure" that seems necessary for accounts, is one of 100 Seers, which might, as proposed above be called a "Saotee." For sub-multiples Mr. Bayley propose *eighths* (at'hees) as more in accordance with Native usage. It is seldom that a less measure appears in commercial accounts than single seers, and therefore there is not so much object in a decimal sub-division.

The objection to the "Seer" proposed by the Bombay Government, which is a vessel holding a Seer of 80 tolas weight of water, or a capacity of 57 cubic inches, is that it is a *misnomer*. If the Native term "Seer" be used at all, it should be the Native idea of a Seer, that is, a vessel containing a seer weight of *grain*. The new Bombay Seer for grain is not what it is supposed to be, and it is no wonder that success has not attended the attempt to introduce what the people consider a deception. A little difference *above* the usual "Seer," would not have been of so much consequence, but this proposed Seer only holds 70 tolas of mixed grain, even when *heaped*. If it were desired to have a Measure analagous to a Seer, to contain a definite number of tolas weight of water, it would have been better to have gauged the Bazaar Seers with water, and have taken the average weight in tolas, about 93, and fixed on that for the standard Seer-measure; The Bombay Government in their Proceedings of the 30th July, 1849, proposed this, but it does not seem to have been acted on but if the "Seer-measure" is *not* to accord at all with the Native

## WEIGHTS AND MEASURES.

Measure, it would be just as easy, and far better on other grounds, to introduce an English Measure of Capacity at once.

The Metrical System which Mr. Bayley would propose for India, as combining more decidedly than any other that he can think of, the three great objects, viz., assimilation to the English system, approximation to the existing Native system, and a means of testing both Weight and Measure of Capacity by the coin of the country, is as follows: I. For *Linear* measure, the English yard and foot, without at present defining the subdivisions. II. For *Land* measure, the Acre, decimally subdivided. III. For *Weight*, the Seer, of 21lbs. avoirdupois corresponding to  $77\frac{3}{4}$  Rupees weight; with a multiple of a "Mun" of 50 seers, (= 100lbs.) and sub-multiples of "Annas" or 16ths of Seers. IV. For Measure of *Capacity*, a "Seer-measure" identical with the English Quart, and defined as containing 97 tolas of water at a temperature of  $84^{\circ}$ , (containing when struck, about a "Seer-weight" of mixed grain) with a multiple of a "Saotee" or 100 seers, and sub-multiples of "at'hees" or eighths.

Mr. Bayley has succeeded in obtaining a decimal subdivision of the Acre in the new Revenue Survey of the Carnatic, and he also had occasion to recommend a decimal notation of the Assay reports of the Madras Mint.

The Natives of India will not of their own accord do what the people of England would not do without a legal enactment, and any Law, must be compulsory. It would have been deemed useless to attempt the introduction of a uniform metrical system by a Proclamation in the Gazette, or by official influence, in England, where all classes of people admitted the inconvenience of so much diversity, and it is not likely that such measures will be successful in India, where the people do *not* admit such inconvenience, and the petty dealers are *directly interested* in a continuance of the present irregularity.

It may be thought that as it is already a penal offence to use false Weights and Measures, the public are sufficiently secured; but there is little use in testing them as long as the Standards are *not defined* by law and the following are a few instances of the inconvenience arising from this laxity.

The first case was one, where the Land Revenue having been fixed originally with reference to the produce and price of grain, complaints were made of its pressure, in consequence of a continued fall (as it was asserted) of price. To ascertain the truth of this, was of much importance, and investigations were made by Government, in the course of which it was discovered that in one District, the official "Price Returns" had been 20 per cent. in error for some years, in consequence of the grain-dealers having altered the capacity of their Measures. In the second case, a merchant at a seaport town sold

## WEIGHTS AND MEASURES.

a certain number of "candies" of copper to a captain of a vessel, who found on re-weighment for sale at Madras, that the weight was short. The seller was able to show that he sold by the Candy where he resided, and if the dispute had not been settled by an amicable arrangement, no official authority could have decided the question, inasmuch as the Candy is so many Seers, and the Seer so many Rupees, but *what* Rupee no one can tell: certainly not the present one, which is some grains heavier than the Rupees of the Native mints, current when the Weights were originally established. In the third case, a long correspondence took place in the Military Department, in consequence of a dispute as to whether a regiment of Sepoys had not overdrawn their rations; it being asserted that the Seer-measure of the town where they were quartered, was too large. The Government requested the opinion of the Board of Revenue, but the only answer they could give, was that the Native "Seer" differed in different places, at the option of the bazaar-men, and that as the Government in their Proclamation had made *no mention of a Seer* for use "in Government transactions," there was no official definition of such a Measure. In the fourth case, the Board of Revenue at Madras were informed that Measures of Capacity were in use in the Town, bearing the Government stamp, and yet differing in capacity from the content prescribed by the Proclamation mentioned above. These Measures were examined, and found to be 4 per cent. in error, but the Stamping Department asserted that they were in accordance with an *old Standard* in their Office, and the Government declined even to prohibit their Seal being affixed to Measures openly at variance with their own Proclamation. All these instances occurred within three or four years, and similar cases happen constantly, for want of some positive law on the subject, and the evil cannot be remedied by a mere Proclamation, which is not binding. It is now 10 years since the Madras Proclamation was published, and models distributed over the country with injunctions to the Public Officers to press their adoption; but with very few exceptions, the attempt has failed, and those very exceptions only add to the discordance already prevailing. It is to little purpose for Government to proclaim a Standard, if its use is not enforced, or if it is not to be considered as decisive in case of dispute. It appears obvious, that where such inconvenient discrepancy and uncertainty exist, it is the duty of Government to decide upon some Standard, and having once decided, not to allow the people the option of accepting it or not. It will often happen that when a practice is insisted on by law, and penalties attached to its infraction, no resistance will be made; whereas if the people are aware that there is no law, and no means of enforcement,

## WEIGHTS AND MEASURES.

their opposition will be most pertinacious and if they can only hold out long enough it must be effectual.

It may be said that in some of the Bombay provinces a new Standard has been introduced with success without legal compulsion. That a reform in the *Weights*—that is, selecting the best known of those already in use—has been partially carried out by the personal influence of some energetic magistrates, is no doubt the case; but as regards the *Measures* of Capacity, a most important branch of metrology to the people of India, the attempt has only succeeded apparently, in one or two instances; and to show how little is to be expected from the progress of education, and march of intellect, the reform has been found impracticable (there being no *law* to enforce it) in the towns of Bombay and Surat, where it might be supposed that official influence and educational enlightenment would have aided the desired object.

Even in those cases where the shopkeepers are *said* to have adopted the new Weights and Measures, assertions are not sufficient. When the subject was under investigation at Madras, Reports were received from two Districts, most positively asserting that the Government Standards were in use; but on subsequently *sending for* Measures actually used in the bazaars, it was ascertained that the Civil authorities had been misinformed completely and Native subordinates err often from ignorance.

All Government transactions, accounts, tariffs, &c., should be in terms of the new System, and in every purchase made by the Public Departments, their own Standard Weights and Measures should be employed. This would supersede the attempts (always futile) to specify on every occasion, in equivalent terms of the authorized standard, the ever varying and uncertain values of the Native Weights and Measures. For general purposes, and as a guide to the Departmental officers, Tables of equalization should be prepared for each District, showing the average results of experiments made to determine the value of the local Weights and Measures. Such Tables though useful, will not of course be conclusive in every case of purchase, inasmuch as Weights and Measures differ in different villages, and the Tables can only give the result of the average of the District. Such Tables have been lately compiled in the Presidency of Madras.

The following memorandum by Mr. Bate, being an Enclosure in a Letter from the Court of Directors of the E. I. Company to the Government of Madras, dated 6th July, 1829, on the occasion of forwarding Standard Weights and Measures in accordance with Act 5, Geo. IV. cap. 74.

# WEIGHTS AND MEASURES.

100°	25129.0		3.5899	139.600

—Mr. W. H. Bayley in No. 4 New Series of Madras Journal of Science for July to September 1857.

Mr. Prinsep remarks that the system of weight established in India by Regulation VII of 1833, was founded on the same unit as the rupee of the equalized monetary system of British India. This unit of the British Indian Ponderary system is called the tola, which weighs 180 grains English troy weight, and from it, upwards, are derived the heavy weights viz:—Chattack, Ser, and Man or Maund; and its subdivisions, the smaller or Jeweller's weights called Mashas, Ratis, and Dhans.

The following scheme comprehends both of these in one series.

Man.	Panseri.	Ser.	Chhatak.	Tola.	Masha.	Rati.	Dhan.
1	8	40	640	3,200	38,400	3,07,200	12,28,800
	1	5	80	400	4,800	38,400	1,53,600
		1	16	80	960	7,680	30,720
			1	5	60	480	1,920
				1	12	96	384
					1	8	32
						1	4

(3013) The "Man" or Maund of 3,200 tolas, is that established by Regulation VII of 1833, and differs from the many weights of the same name throughout the country.

(3014) Panseri from پانچ five and پسر ser, as its name denotes, is a five ser weight.

## WEIGHTS AND MEASURES.

(3015) Ser سیر A Ser, is the commonest weight in use in the retail business of the bazars of India, and as it varies in quantity with the article sold, it has to be described as the Ser of so many tolas. The standard or Bazar Ser of Bengal, being always 80 tolas. The Ser of salt is 82 tolas.

(3016) Chhatak from چھ Six and ٹیکا marks, is the lowest denomination of the gross weights and is commonly divided into halves and quarters (called in Bengali kachha), thus marking the line between the two series, which are otherwise connected by the relation of the ser &c. to the tola.

(3017) Tola تولا The tola is chiefly used in the weighing of the precious metals and coins.

(3018) Mashas ماشه Ratis رتی and Dhans دھان are used chiefly by native goldsmiths and jewellers. They are also employed in the native valuation by assay of the precious metals.

The following table will show how far the Indian system of weights corresponds with the Troy weights of England and with the "Système métrique of France." The coincidence of the former is perfect: and in the latter, the masha nearly accords with the gramme and the ser with the kilogramme.

British Indian Weights.	English Troy Weights.				French Weights.
	lbs.	oz.	dwt.	grs.	grammes.
One Man. ... ..	100	0	0	0	37320.182
One Ser ... ..	2	6	0	0	933.005
One Chhatak ... ..	0	1	17	12	58.310
One Tola ... ..	0	0	7	12	11.662
One Masha... ..	0	0	0	15	0.972
One Rati... ..	0	0	0	1.875	0.122

The following scale will suffice for the conversion of English Troy weights into those of India.

lb. Troy.	Oz.	Dwt.	Grains.	Tolas and Decimals.
1	12	240	5760	32.000
"	1	20	480	2.6666 etc.
"	"	1	24	0.1333 etc.
"	"	"	1	0.0055 etc.

The following are a few of the valuations for the principal weights of Europe, etc. extracted

## WEIGHTS AND MEASURES.

from Kelly's Cambist, p. 222, the weights in Troy grains have been converted into tolas by dividing them by 180.

Place and Denomination.		Weight of a single lb. mark &c. in tolas.	Number equal to 1 man or 100 lbs troy.

Rome,	Libbra.....	29.077	110.049
Russia,	Pound.....	35.102	91.161
Spain,	Mark.....	19.725	162.230
Venice,	Mark.....	20.452	156.457
Vienna,	Mark.....	24.072	132.933

At Madras the 'man' is assumed as equal to 25 lbs. avoirdupois: and at Bombay the more convenient equivalent of 28 lbs. or one quarter cwt. has been adopted for the standard man.

The ser at Madras contains 8 palams, of 10 pagodas each, so that like the ser of Bengal it has the subdivision into 80 parts. In the Malabar system also used at Madras, 2½ palams (1 fanam) make a ser, and the tola occupies the place of the man; it is equal to 23.192 lbs.

The ser at Bombay is divided into 30 pa'is or 72 tanks or 72 grains troy each.

(3019) Tank, as now existing in Bombay is 72 grains. In Dharwar it is 50 grains and in Ahmednuggur it is 268 grains.

Man. The man system follows the common scale; viz:

16 Chhataks = 1 ser.

40 sers = 1 man.

20 mans = 1

khandi or mani.

Panseri. The use of a five ser weight also universally prevails under the name of Panseri, dhari or visa. The dhari from its name however, seems to be properly a measure, and accordingly, while in Malwa it is equal to 5 sers, in other places it is found of 4, 4½, 5½, 10, 11, and 12 sers.

(3020) The terms adhola or adheli half; pao or powah, quarter; adhpao half quarter, explain themselves.

## WEIGHTS AND MEASURES.

### (3021) *Dry and Liquid Measures.*

India does not, properly speaking, possess dry or liquid measures. Where these are employed, they depend upon, and in fact represent the ser or man weight and the value of a vessel of capacity rests solely on the weight contained in it. The mode in which this is effected for the dry measures of the south and west of India is by taking an equal mixture of the principal grains, and forming a vessel to hold a given weight thereof so as to obtain an average measure: sometimes salt is included amongst the ingredients. Trichinopoly is the only place where grain is said never to be sold by weight. The markal (properly Marakkal, from the Tamil) and para are the commonest measures: the latter is known throughout India. In Calcutta it is called ferra and is used in measuring lime etc: which is still recorded however in mans weight. In its weights, Southern India retained, from the ancient Metrology of the Hindus, most of the names and terms properly hindu, پالا pala, تولا tula: visa; بھارا bhara; khari; (? khandi), baha. Throughout the Moghul empire on the contrary, the ser and man were predominant. The word 'man' of Arabic or Hebrew origin, is used throughout Persia and northern India, but it represents very different values in different places. Thus the man of Tabriz is only  $6\frac{1}{2}$  lbs. avoirdupois, while that of Palloda in Ahmednuggur, is  $163\frac{1}{4}$  lbs. The Man of India varies principally as follows:

Man of Bengal, containing 40 sers, and averaging 80 lbs. avoirdupois.

Man of Central India (Malwa Ajmere, &c.)	20 sers & ...	40 ...
„ „ Gujarat & Bombay	40 ... & =	28 ...
„ „ Southern India	... ..	25 ...

There are however, many other varieties of mans, from fifteen to 64 seers in weight, which it is unnecessary to particularize.

By the British enactment of the 1st January 1826, one imperial measure was established as a substitute for the variable wine, oil and corn gallons of England, with their multiples and divisions. This imperial gallon was made to contain 10lbs. avoirdupois weight of distilled water, weighed in air at the temperature of 62° Fahr. the barometer standing at 30 inches. It has a capacity therefore of 277.274 cubic inches, and the following are a few useful derivatives from this unit.

## WEIGHTS AND MEASURES.

Indian Weights.

1 pint...	...	...	...	...	...
2 „ = 1 quart	...	...	...	...	...
8 „ = 1 gallon	...	...	...	...	...
64 „ = 8 „ = 1 bushel	...	...	...	...	...
512 „ = 256 „ = 64 „ = 8 „ = 1 quarter.	...	...	...	...	...
2048 „ = 1024 „ = 256 „ = 32 „ = 1 Chaldron.	...	...	...	...	...

The gallon nearly corresponds with the Panseri or dhari of the Indian. Corn measures while the bushel bears the same proximity to the man weight.

The following is the scale of measures in use at Madras.

		Cub. In.	
1 Olluk	=	11.719	
8 Olluks	=	1 Padi	= 93.752
8 Padis	=	1 Markal.	= 0.750 = 27lbs. 2oz.
5 Markals	=	1 Parra	= 3.750 2dr. water.
400 Paras	=	1 Garce	= 300,000

(3022) *Garce*, TEL. Garissa a Madras measure of 400 paras.

(3023) *Olluk*, HIND. ولی a Madras measure of 11.719 cubic inches.

(3024) *Padi*, TAM. a Madras measure of 8 Olluks.

(3025) *Marakal*, TAM., a Madras measure of 8 Padis.

## WEIGHTS AND MEASURES.

(3026) *Paṭra*, TEL., a Madras measure of 5 Markals.

(3027) *Ceylon*. The dry measure of Ceylon, is thus given in the Oriental Metrology.

		gallons.	inch.
4	Cutchundoos = 1 Ser	= 0.24	= 4.35 dram. + 4.35.
4.8	Sers = 1 Coornuly	= 1.15	
2.6	Goornis = 1 Markal	= 2.88	
2	Markals = 1 Parra	= 5.76	= cube of 11.56 ins.
8	Parra = 1 Amonam	= 46.08	= 5½ bushels.
8½	Amonams = 1 Last	= 432	= 6½ quarters.

(3028) Linear Measures.

(3029) *Biswa* from بیس HIND., Twenty, is the twentieth part of a Beegha, and besides being a measure of land, is also used to signify the extent of proprietary right in an estate. Each estate or village is considered an integer of the Beegha which is divided into imaginary Biswas and Biswansees, to show the right of any particular party. Thus the holder of 5 Biswas is a holder to the extent of one fourth of the entire village; precisely in the same way as the *As* was used amongst the Romans. Thus, *heres ex summuncia*, heir to one-twenty fourth;—*heres ex dodrante*, heir to three fourths;—*heres ex asse*, sole proprietor. In the same manner, *bes*, *bessis*, was used to express a *biswa* *berar*,—*socius ex besse*, and thus in sound and meaning, for of course there is no real connection, there is a close resemblance between the words. *Bes* when it was thus applied as a Sub-division of the *As*, was the eighth part of a Jugerum or acre; not, as is usually applied, two thirds.

(3030) *Coss* کوس HIND. The itinerary measure of India, of which the precise value has been much disputed, chiefly on account of the difficulties which attend the determination of the exact length of the Gaz or Yard. The Ayeen-i-Akberree lays down distinctly that the Coss consists of 100 cords (tunab), each cord of 50 Gaz; also of 400 poles (ban), each of 12½ Guz: either of which will give to the Coss, the length of 5,000 Gaz. The length of the Coss, as ascertained from the average distances of the old Minars or Coss pillars, is = 2 miles, 4 furlongs, 158 yards. In different parts of India however, these vary.

The *Guzeratee Coss*, is the greatest distance at which the ordinary lowing of a cow can be heard, which is determined to be 50 Jureebis or 15,000 Guz. This Coss resembles the Chinese *lih*, i. e. the distance which can be attained by a man's voice, exerted on a plain surface, and in calm weather. Another in Bengal, is estimated by plucking a green leaf and walking with it till it dries. Another is measured by a hundred steps made by a woman carrying a jar of water on her head and a child in her arms. All these are very indefinite standards. The same may be remarked of the Oriental *meel*, as well as the European mile and league. The two former evidently derive their name from the Roman *Milliare* and the difference of the value proves that the mere name was borrowed without reference to

## WEIGHTS AND MEASURES.

its etymological signification. According to the *Kamoo*s, the oriental Meel is a lax and vague measure, but it has been considered by Dr. Lee to be to the English one, as 139 to 112. The league also, from the German *legen*, to see, and signifying the distance that can be readily seen by the eye on a plain surface, is as indefinite as a Guzeratee Gao, and a Bengal or Dhuppea Coss. Coss, is an Indian word: the equivalent in Persian is Kuroh کروه, the same as the Sanscrit word Krosa, of which four go to the *Yojan*, about the precise value of which different opinions are held, four English miles according to Bopp; 4½, 5 and 9 miles according to Professor Wilson; but according to the distances in Fi Hians route, the *Yojan* in his time, was equal to seven English miles, and this agrees much better with what we find the *Yojan* to be when we resolve it into its component parts.

8 Barley corns = 1 finger

24 = 1 Dund

1000 = 1 Krosa

4 = 1 Yojan

and estimating the fingers breadth at eight barley corns, this makes the *Yojan* equal to six miles, one hundred and six yards, and two feet.

In the Linear Systems of India, the basis of all is the same, the cubit or human forearm: and this unit is found in Oriental countries as well as in the West, divided into two Spans and 24 fingers' breadths. Thus under the Hindu princes, the hath (in Sanscrit hasta) was equal to two *vitesti* or spans and to 24 *angula* (angula). The *angul*, finger, is divided into 8 *jau* (Sanskrit yava) or barleycorns. 4 Hathas or cubits = 1 danda or staff: 2000 dandas make = 1 Krosa or kos, which by this estimation should be 4000 yards English or 2½ miles. The *Lilavati* states that 10 haths make one bans or bamboo and 20 bans in length and breadth = 1 *niranga* of arable land.

Natives of India continue speaking of the *hath* or cubic, alluding to the natural human measure of 18 inches, more or less, and it is practically used in measuring off cloths, ribbons, &c., and in taking the draft of water of a boat. In many places also, in Bengal and in Southern India, the English cubit has been adopted as of the same value as the Native measure.

In Burmah, the people seemingly use a linear measure of this name, consisting of the natural cubit plus a band breadth, which would be about twenty inches.

(3031) *Doncha* دونچا four and a half. A word in use with the surveying Ameens of India, when reducing their linear measurements to Beeghas; the other words used by them in fractional multiplication are,

Deorha	1½	Poncha	5½
Dhuma	2½	Khoncha	6½
Honta	3½	Sutoncha	7½
Dhoncha	4½		

## WEIGHTS AND MEASURES.

The size of the fields rarely require the Ameens to go beyond this.

In Madras, Sir Thomas Munro established a measure (called a ground or mani) of  $60 \times 40$  or 2,400 square feet, of which 24 make a kani = 57,600 square feet, = 6400 square yards, or exactly equal to four Bengal Bighas.

The Madras kani is to the English acre, as 1 to 1.3223, or as 121 to 160 nearly.

In Chingleput, the *adi* or Malabar foot is used, which is 10.46 inches : 24 *adis* = 1 kali, and 100 square kalis = 1 kani or nearly an English acre. The common kali however is 26 *adies* or  $22\frac{1}{2}$  feet which makes the kani = 1 acre,  $28\frac{1}{2}$  *perches*.

(3032) Guz. گز or yard. The *Ilahee* Guz of Akbar is assumed by the British Government of India to have been 33 inches. The value of this measure varies in different parts of India. In some places the English yard of 36 inches is understood and will doubtless soon supersede all other values ; but the term *gaz*, is one of Mahomedan introduction.

The Akbari *gaz* for cloth measure = 46 fingers =  $34\frac{1}{2}$  English inches.

The *Ilahi* *Gaz*. established by Akbar as the sole standard measure of the empire = 40 fingers =  $30\frac{1}{2}$  English Inches.

The Akbari *beegha*, of 3600 square *gaz*, = 2600 square yards = 0.538 or somewhat more than half an acre, on the above estimation.

The *Ilahi* *gaz* of Akbar was intended to supersede the multiplicity of measures in use in the 16th Century ; and in a great degree it still maintains its position in the Upper Provinces of India. In general however, different measures are employed in each trade, and the cloth merchant in particular has a distinct *gaz* of his own.

(3033) *Jureeb*. جريب Persian. A measuring chain or rope. Before Akbar's time it was a rope, but he directed it should be made of bamboo with iron joints, as the rope was subject to the influence of the weather. European surveyors use a chain. A *Jureeb* contains 60 *Guz*, or 20 *Gut*, has, and in the standard measurement of the upper Provinces of India, is equal to 5 chains of 11 yards, each chain being equal to 4 *Gut*, has. A square of one *jureeb* is a *Beegha*. Till the new system of survey was established, it was usual to measure lands paying revenue to Government, with only 13 knots of the *Jureeb*, which was effected by bringing two knots over the shoulder of the measurer to his waist. Rent free land was measured with the entire *Jureeb* of 20 knots. A *Jureeb* in Hebrew and Arabic signified originally only a measure of capacity, equal to 4 *Qufeez*, or 384 *Mud*, (Latin *modius*) and in course of time came to signify the portion of land which required as much to sow it as a *Jureeb* would contain. The *Pat*, *ha* and *Nalee* of Garhwal and Kumaon have a

## WHALES.

similar origin.—*Prinsep's Antiquities*, by Thomas, pages 96, 7, 8, 107, 112, 4, 126, 129, 130.

At the cession of the Carnatic besides the Chittoor Pollams in N. Arcot there were the 2 large Zemindaries of Calastry and Cavetnaggur the latter also known as Bom Rauze's country. Throughout the latter country (Bom Rauze's) the foot of the village God of Nanaveram was always taken as the unit of Land Measurement of which

64

100 Goontah in Poongee.

= 1 Cawnee.

12 or 15 in Nungee.

(3034) WELLS are often sunk in the alluvial soils of India, as foundations for architectural structures.

(3035) WHALES. The following kinds occur at Japan. *Kud suri*, Jap. is caught frequently about Japan, but particularly in the Sea *Khumano*, which washes the Southern Coasts of the great Island Nipon, as also about the islands Tsussima and Goto, and upon the coasts of Omura and Nomo.

*Sebio*, Jap. is the chief, and indeed the largest of the whale kind. It affords most train-oil, and its flesh is very good, and wholesome, so far that fishermen and the common people attribute their good state of health amidst all the injuries of cold and weather, which they are continually exposed to, chiefly to their eating this flesh.

*Awo Sangi*, commonly *Kokadsura*, that is a small whale, is gray or ash colored, smaller than the *Sebio*, from which it also differs something in shape.

*Nagass*, Jap. is commonly 20 to 30 fathoms long, and has this particular, that it can stay under water for two or three hours, during which time it can travel a vast way, whereas other whales must continually come up to the surface of the water for fresh supplies of air.

*Sotookadsura*, Jap. that is, the whale of blind people, so called from the figure of a *Bijwu*, a sort of Lute, which blind people in Japan use to play upon, which is said to be naturally represented on its back. It is not a very large sort, and seldom exceeds ten fathoms in length. It is caught frequently about Japan, but the flesh is reckoned unwholesome food, being as they say too hot, and occasioning coughs, fevers, eruptions on the skin, and sometimes small-pox. It is brought to market with other fish, and sold for the flesh of the *sebio*, but those who know it will never buy it.

*Mako*, Jap. never exceeds three or four fathoms in length. This same name is given to the young ones of the other kinds. This is caught frequently upon the Eastern Coasts of Japan, as also upon the coasts of *Kij nokuni* and Satzuma. Ambergris is found in the intestines of this Whale. The head yields a small quantity of train-oil.

*Iwasikura*, (Japan,) that is Sardin's Eater, has a tail and fins like common fish. They saw this sort when we went up to court between *Oamino*-

## WINES OF PERSIA.

*Al and Simmoseki* and Kæmpfer took it to be that which the Dutch call *Noord Caper*. Of all these several kinds of whales nothing is thrown away as useless, excepting only the large *Shoulder* bone. The skin which is black in most kinds, the flesh which is red and looks like beef, the intestines, which from their remarkable length are called *Feakfirs*, that is, an hundred fathoms long, and all the inward parts are eaten pickled, boiled, roasted, or fried. The fat or blubber is boiled into train-oil, and even the sediments of the second boiling are eaten. The bones, such as are of a cartilaginous substance, are boiled when fresh, and cut, or scraped, cleaned and dried for the use of the kitchen. Several little things are made of the jaw-bones, fins and other bones, which are of a more solid substance, and particularly their fine steel-yards for weighing gold and silver are made of them, and have borrowed their name from thence.—*Kæmpfer's History of Japan*, V. I. p. p. 133, 134.

(3036) WINES OF PERSIA. Persia is supposed to be the native country of the vine; and this opinion seems to receive confirmation from the extraordinary perfection to which its fruit there attains. "Grapes," says Oliver, in his description of the country round Ispahan, "every where abound, and their quality is excellent. None of those which I had tasted at Constantinople, in the islands of the Archipelago, in Crete or Cypress, in Syria, in Province, or in Italy, appeared to me comparable to the *Kismis* grape, of which the berry is white, of an oval shape, and middling size, having a very delicate skin, and no seeds." [*Voyage dans l'Empire Othoman*, Tom. III. p. 108.] At Shiraz, they are described as growing "to a size and fulness hardly to be matched in other climates." [*Travels in Georgia and Persia* by Sir R. Kerr Porter, V. I. p. 706.] "But, according to Mr. Morier, even grapes of Shiraz are surpassed in quality by those of Casvin. That city," he observes, "is environed by vineyards and orchards to a considerable extent, the former of which yield a grape celebrated throughout Persia for the good wine it produces. The vine-dressers water their vines once in the year, which is twenty days after the festival of the Noroz, about the 10th of April; and the vizier mentioned that the soil, which is clayey, is so good, that the moisture it imbibes suffices until the next irrigation." [*Second Journey through Persia*, p. 203.]

The Mahomedan Religion, prohibiting the use of wine to its followers, tends to restrict the manufacture to those places where the Jews, Armenians, or Hindoos, form part of the population. But the Persians have always been less scrupulous observers of this precept of the Koran, than the other Mahomedans; and several of their Kings, unable to resist the temptation, or conceiving themselves above the law, have set an example of drunkenness, which has been very

## WINES OF PERSIA.

generally followed by their subjects. Shah Abbas II., as we learn from Chardin and Tavernier, was much addicted to wine, and made his courtiers share in his cups. His cellars were abundantly stocked with the choicest vintages of Georgia, Karamania, and Shiraz, preserved with great nicety in bottles of Venice crystal; and, every six weeks, he received from the first of these countries a supply of twenty chests, each of them containing ten bottles, and each bottle about three quarts. He had also, at different times, wines sent him from Spain, Germany, and France; but he drank only those of Persia, thinking them preferable to all others. A particular officer was appointed to superintend his wines, and to watch the proceedings of all those who made or sold that commodity; no one being permitted to engage in the trade without an express licence, which was only to be obtained by dint of bribery. [*Voyages en Perse*, Tome III. p. p. 26, 249] At present many Persians indulge secretly in wine, and generally to intemperance; as they can imagine no pleasure in its use, unless it produce the full delirium of intoxication. They flatter themselves, however, that they diminish the sin, by drinking only such as is made by infidels: for "so great is the horror of a Mahomedan vintage," as a late traveller informs us, "that, whenever jars of the wine of Shiraz are discovered, the chief officers of the town are ordered to see them broken to pieces. But all this strictness relates to the Persians alone. [*Travels in Georgia and Persia*, by Sir R. Kerr Porter, V. I. p. 348.] "The Jews and Armenians prepare wine on purpose for the Mahomedans, by adding lime, hemp and other ingredients, to increase its pungency and strength; for the wine that soonest intoxicates is accounted the best, and the brighter and more delicate kinds are held in no estimation among the adherents of Mahomed. [*Voyages de Chardin*, Tom. II. p. 67.] It is chiefly along the line of mountains that stretch from the Persian Gulf to the Caspian Sea, that the best wine districts are situated. Besides the vintages of Shiraz, those of Yezd, Ispahan, &c., are mentioned with commendation by Chardin; and recent travellers add to the list the growths of Teheran, Tabriz, and Casvin. But few of these wines, except the Shiraz, are much known out of the country where they are produced; and even the last mentioned no longer maintains the high celebrity which it formerly enjoyed. Tavernier estimated the quantity annually made at four thousand one hundred and twenty-five tuns, of which a considerable portion was shipped for the East Indies; but both the manufacture and trade in the commodity have declined after the wines of Madeira came into general use in our Asiatic territories.

The principal vineyards in the environs of Shiraz are situated at the north-west of the town, where

## WINES OF PERSIA.

the soil is rocky, and the exposure extremely favourable. The vines are all kept low but occasionally supported by stakes. Among the species cultivated, one of the most esteemed is the *Kismis*; the fruit of which, having an agreeable acidulous taste, is in great request for the table, as well as for the manufacture of wine, and when dried, forms an excellent substitute for currants. Next to it comes the *angoor asji*, a black, or dark purple grape more fleshy than the other, and yielding an excellent red wine, of a deep red colour, and somewhat astringent taste, which Kæmpfer compares to Hermitage: but the quantity made is small. For the more common wines, or those which most frequently come into the market, five different kinds of grapes are used, of which four are white or brown, and the fifth, called *Samarcandi*, from the town of that name, has a black skin with red juice, and furnishes a claret wine. At Ispahan a mucadel grape is grown, which yields a copious supply of must.

When the grapes are gathered, they are brought to the cellar, and introduced into a vat or cistern, formed of masonry, and lined with plaster, about eight feet in length and breadth, and four in depth, where they are trodden; and the juice that flows from them is collected in a trough at the bottom, from which it is immediately removed into large earthen jars, to undergo the requisite fermentation. These jars, which contain from sixty to eighty gallons, and are either varnished in the inside, or rendered impervious by a coating of grease, are carefully covered, and left undisturbed for a couple of days. When the fermentation has fairly commenced, the murk is stirred by one of the workmen with his arms bare; and this operation is repeated for eighteen or twenty successive days. The wine is then strained, through coarse sieves, into clean vessels, which are filled to the brim, and covered with light matting. In these it is allowed to remain for thirty or forty days, and when the secondary fermentation is thought to be completed, it is racked into smaller jars or bottles, in which it can be conveniently transported. That which is destined for exportation is strained a second time. The larger bottles, called *Karabs*, are covered with wicker work, and hold eight or nine gallons,—the smaller, six or seven quarts. They are packed in chests, which generally contain ten small bottlee, or two *Karabas*, and one small bottle between. [Kæmpfers, *Amœnitates Exoticæ*, p. p. 374-8.] The bottles are stopped with cotton, soaked in wax or pitch.

Chardin found the Shiraz wine of excellent quality; and, though inferior in delicacy to the vintage of his own country, and at first somewhat rough to the taste, yet, after drinking it for a few days, he relished it so much, as to give it the preference to all other wines. He admits however, that it does not keep well, being liable to rousiness after

## WITTOBA.

the second year; and that, when drunk freely, it is apt to cause headache. Kæmpfer extols it more highly, placing it, in point of flavour and aroma, on a level with the best growths of Champaign and Burgandy, and contradicting the assertion, that it incommodes the head. [Amœnit Exotic. p. 379.] Since these travellers wrote, and since Hafiz sung the praises of the ruby wine of Shiraz, the declining demand, and the difficulties opposed to the manufacture, have probably tended to impair the quality; for we are told, that, at the present day, "the culture of the vine itself is comparatively neglected at Shiraz; the sorting of the fruit is a delicacy seldom attended to; and the apparatus used in the compression, fermentation, &c. of the juice, is on so confined a scale, that only small quantities of the esteemed flavour are obtained. Indeed, no wine, under one name, possesses such variety of quality; every gradation, from a liquid clear as the most brilliant topaz, to a sour and muddy syrup. When good, the taste should be a little sweet, accompanied with the flavour of dry Madeira, to which, when old, it is not at all inferior [Travels in Georgia and Persia, V. I. p. 707.]

This description of the colour and flavour of the Shiraz wine, however, applies only to the white sort, which, even when of firm and generous quality scarcely deserves to be ranked on a par with the best growth of Madeira, some samples of it betray a slight taste of saffron, which is not unfrequently added by the Armenian manufacturers to their wines, in order to please the eye as well as palate of their customers. The other kind, which is probably the bright-red wine described by Chardin, resembles tent, or the second rate sweet wines of the Cape, and occasionally tastes a little of the pitch used for stopping the bottles in which it is exported. It is not so durable as the white.—*Henderson's History of Ancient and Modern Wines.*

(3037) WITTOBA. Wittoba is a Hindoo idol worshipped at Alundi, but his principal shrine is at Punderpoor, on the Bheema, to the westward of Sholapoor. Wittoba is one of the many subordinate incarnations of Vishnoo. It took place at Punderpoor, a town about eighty miles to the Southeast of Poona. More relates the history of this incarnation. It conveys, unlike most Hindoo legends, a moral lesson.—*Chow Chow*, p. 251.

The three principal gods of the Hindoos, are Vishnoo, Siva, and Bramah, and the three goddesses Doorga, Luckshmi, or Luximee, and Saraswatee Doorga or Durga, is often called Parvati or Parbuttee, or Bowan, Bowanee, or Bhowani. Kali or Kalee, sometimes Devi, and she is spoken of under all these several denominations.

Wittoba is a god of very questionable orthodoxy, but he is very popular among the Mah-rattas, and, therefore, the Brahmins admit him with the best grace they can into their Pantheon. The same is the case with Kundoba, who is yet

more popular among the lower orders of Mah-rattas, and, if possible, less orthodox; they are probably the ancient deities of the Mahratta race, which the Pantheistic spirit of Brahminism has admitted as Hindu divinities.—*Ward's Literature and Mythology of the Hindoos.*

In Isaiah lvii. 6, where the Jews are reproved for their idolatry, stones are mentioned as one of their objects of worship. "Among the smooth stones of the stream is thy portion, *they*, they are thy lot, even to them hast thou poured out a drink offering, thou hast offered a meat-offering. Should I receive comfort in these?"

Veneration for stones may be traced among all nations; the following instance from Scripture reminds one strongly of Hindoo simplicity. "And Jacob rose up early in the morning, and took the stone he had put for his pillow, and set it up for a pillar, and poured oil on the top of it. (Gen. xxviii. 18)—*More's Hindoo Pantheon quoted in Chow-Chow.*

(3038) WOOD. In Bombay in 1848, when the whole of the wood, stored in the great enclosure at Mazagon, occupying the space betwixt the Hope Hall Hotel, the Railway station, the Byculla main road and the shore, was burnt, an attempt was made to convert the vast mass of pure white ashes which remained, into potash. The taste was alkaline, and the conviction was reasonable that wood here, as elsewhere, if completely burnt under exposure to the air would yield potash. It turned out, that in place of this, the whole product of combustion was caustic lime, and this seemed equally to hold good with all trees, whatever their kind. The enquiry was pursued in reference especially to trees burned in the jungle, when the results seemed the same. In reference to many of these last, a curious fact transpired; a tree once set on fire, burned leisurely and quietly almost without flame, not only to the extremities of the branches, but underground to the extreme ramifications of the roots, and this occurred in the case of perfectly sound and healthy trees, full of sap, as well as in the case of those that were dead and dry. The conclusion drawn from these results is, that in these cases nitre, or some other substance tending to promote combustion, must exist in the sap of the tree. Resolved that these results should be removed from the field of conjecture to that of fact, Dr. Giraud commenced a series of experiments, the result of which we hope speedily to see before the world. It seldom happens that the core of trees is exactly in the centre; they seem in Europe, to thicken most rapidly in the direction in which they are most exposed to light and heat. Scotch fir, thus exposed, measure twice as much in this direction as in the opposite. From a very limited number of experiments made on seven-year old saplings here, it appears that, in this time a healthy *Casuarina* will attain an altitude

of 50 feet, and a circumference, a foot above the ground, of 30 inches. At the base, the section has the form of that of a pear cut lengthways, the larger diameter being 10 inches, the shorter 7. Measured across the core, we find the one radius  $9\frac{1}{2}$  inches, the other  $3\frac{1}{2}$ , or nearly double that of the Scottish fir. In another tree of the same age 45 feet in length, two feet in girth, the greater diameter was 8 inches, the lesser 6—the larger radius being 5 inches, the lesser 3. Taking the tree in lengths of ten feet from the root, the seven rings continue to the last, the innermost having extended themselves upwards to the very top as the tree grew. But the eccentricity of the core has now greatly diminished, and the stem becomes nearly round—the predominance of the mass continuing on the same side as at the root. These peculiarities are most conspicuous in the *Casuarina*; but they manifest themselves, more or less in all trees. An Indian Rubber tree planted in 1851, attained a diameter of 7 inches, the core being  $4\frac{1}{2}$  inches from the one side, and  $2\frac{1}{2}$  from the other; the two grew side by side. Very nearly the same law holds good with a Teak and an Acacia. In Europe the thickening is always on the south side of the tree: here, so far as it appears, it is in general mostly due west. In all likelihood the excess of solar heat furnishes the explanation in both cases. North of the Tropics, the sun always shines more or less from the south, and gives out more heat from this than from any other direction. From the Tropics to the Line, the sun is so nearly vertical, that the mass of heat contributed to a tree or any other body perpendicular to the earth, is from east or west. But from dawn till noon the temperature of the sun is comparatively moderate—it is from mid-day till sunset, that the vast mass of heat is thrown off, the rays shooting from the westward. In this direction a tree thickens on the same principle that it expands in Europe to the southward. As these researches are pursued, we trust that they will help to assist us to that marvel of vegetable life—the silicification or petrification of the living trees. We are all familiar with the spongy stony substance called Tabashir, deposited at the joints of the bamboo. The fact is generally known that the Teak tree often becomes in part petrified,—that is the deposition of silica becomes so abundant, as to turn a portion of the trunk into stone, usually resembling the petrified wood of Egypt, Sindh, Goozerat, and Trevicary, &c. In Upper India this is not at all confined to the bamboo or the teak—both remarkable for their siliceous secretions,—forming in the former a beautiful enamel all over the stem, furnishing the sharp points of the leaves, and making the upper surface of the leaves of the latter eminently serviceable as sand-paper. The Ghunbhar wood found in the Nepaul and Chittagong forests contains such quantities of silica that the car-

## YEZDEZIRD.

penter who contracts to saw it by the foot, makes it a condition in his bargain—that it shall contain no stone. The Ebony and Sissoo, and the Sit-Sal or jungle rose-wood, contain these secretions, though in much smaller quantities. The most mysterious circumstance connected with the specimens from our petrified forests is, that for every atom of carbon or other organic matter that has been removed, an atom of silica has come in its room, the structure remaining so perfect, that under the glass it could not be discovered whether it was a petrified or living specimen we were examining. The experiments of Sir Humphrey Davy shewed that, in Europe, the durability of woods—that is, their capacity of remaining uninjured through long lapses of time,—was proportioned to the weight of charcoal yielded by them, and that there were many woods, heavy of themselves, that left but a small proportional residuum in the retort after destructive distillation. We doubt if anywhere in Europe a piece of timber can be produced known to have existed 800 years; it would be curious to test the fragments of teak which have formed the supports of the ceiling of the caves of Salsette, which must have been in their places for above two thousand years, and are therefore, the oldest pieces of timber known to man.

We fear we may have ventured too far in an attempt to describe an experiment just begun, where the number of facts brought to light is too

## YEMEN.

small for generalization; where we confess ourselves to be too slightly acquainted with the subject, to feel certain that we may not have given familiar facts as novelties, or even misemployed a familiar and commonplace nomenclature. Our object has been, to induce others to come forward and assist in promoting an enquiry which approves itself even to the least informed, as in the last degree interesting. It seems to us, little conversant as we profess to be in such things, considering the vast extent, and the extreme fertility of the field, that the aspirants after University honours, could in no way better wipe away the reproach generally attaching to them,—that they could do nothing but learn by rote, imitate or parrot,—than take up for themselves, and carry through unassisted, some branch of enquiry such as that now under consideration, where the facts are within the reach of every one; where sharp and shrewd-witted observation and self-relying originality may easily supply all that is required. They may rely on it, that there are fifty reputations to be made within the island of Bombay by the possession of a little leisure, and a moderate measure of intelligence, observation and reflection.—*The Bombay Standard. November 19, 1858.*

(3039) WUSEEAT NAMEH, Arab. A will.

(3040) WUZZOO AND TYAMMOOM. Arab. Two forms of ablutions prescribed for Mahomedans before engaging in prayer.—*Herk.*

## Y.

(3041) YAK. *Bos grunniens.*

(3042) YAVANA the term by which, in ancient India the Greeks were known.—*Prin. Ind. Ant.*

(3043) YEZDEZIRD, the forty-fifth King in descent of the race of Kaimurs, with whom ended that Persian Monarchy, in the middle of the Christian era, when the Caliph Omar invaded Persia, and in a fierce and well contested battle at the village of Nahavand, about fifty miles from the ancient city of Ecbatana, the fate of the empire was decided, the Persian Army, numbering 15,000 men being defeated with great slaughter. Yezdezird abandoned his kingdom, as lost, and after wandering in disguise for a period of ten years, was treacherously slain in A. D. 651, by a miller to whom his secret had been confided. This event terminated the Sassanian dynasty and the Monarchy founded by Kai Khosroo, the Cyrus the Great of the Greeks.

The era of Yezdezird the 3rd or the Persian Era began on the 16th June A. D. 632. The year consisted of 365 days only, and therefore its commencement, like that of the old Egyptian and Armenian year anticipated the Julian year

by one day in every four years. This difference amounted to nearly 112 days in the year 1075, when it was reformed by Jelal-ood-din, who ordered that in future the Persian year should receive an additional day, whenever it should appear necessary to postpone the commencement of the following year, that it might occur on the day of the sun's passing the same degree of the ecliptic.—*Prinsep's Antiquities by Thomas.*

(3044) YELLANDE, Ziziphus Jujuba? the Malaya name of a tree which the natives use for general purposes. It produces a fruit from which they extract a sweet scented oil, which is used medicinally; and also for the hair of the women on days of ceremony.—*Edye. M. and C.*

(3045) YEMEN. The province of Yemen, which comprises Aden, lies in the southern part of Arabia, and is washed on the west by the Red Sea, and the south by the Indian Ocean. It is of great extent, comprising nearly 70,000 square miles, and consists of two natural divisions, the upper or mountain district, and the lower country called Tehameh. The lower country comprises many desert and sandy tracts.

## YEMEN.

still, notwithstanding the scarcity of water, there are several towns and hamlets on and near the sea coast. Along the shore, are numerous small islands, interspersed with coral reefs. Amongst these little islands, is that of Tarsen, celebrated for its grotto of pearls. In this district the Beni-Halal Bedawins are the principal tribe. They are very poor, and live principally by plunder.

Tehameh proper occupies the level country lying between north Yemen and Aden. In the north of Tehameh is Lohaya, an Arab settlement consisting of a few stone houses and a number of mud huts. The harbour is good, and the trade in coffee considerable. The island of Kamran, lying about eighteen miles south of Lohaya, has a better harbour than the latter place, and is much frequented by vessels going from India to Jeddah, as here they can be supplied with wood, water, and provisions. Farther south along the coast is the town of Hodeida, having an excellent port, fortified by a small citadel. The town is under the rule of a dola or pasha, and yields a considerable revenue by the tax imposed on coffee.

But the principal coffee-mart in Arabia is Beit-el-Fakih, situated at a moderate distance from Mokha, and near the mountain regions where the berry grows. The town is of some extent, lying round the citadel, which is built in the centre. Though many of the dwellings were originally constructed of stone, they have become untenable owing to the depredations of a small white ant. Passing along the coast, we meet many cities and villages until we reach the capital of Tehameh. Zebid, so the town is called, lies near one of the most beautiful and well irrigated valleys in the country. Though still possessing many mosques and other public buildings, with a handsome aqueduct, much of its ancient regal splendour has departed. However, Zebid still possesses an academy where the youth of Yemen and Tehameh receive a liberal education, according to modern Arabian ideas, and is besides one of the chief meeting-places where the merchants of Egypt, Arabia, and Persia assemble. Farther south lies the celebrated town of Mokha, four centuries old, and second in importance only to Zebid.

This portion of Yemen that we have described is the least fruitful of the province, but the remainder merits the appellation of "felix" or happy, by which this portion of the great peninsula, was distinguished amongst the ancients. The whole tract is divided into separate portions, by mountains intersecting fertile valleys, and the inhabitants, thus parted, naturally formed themselves into little independent states. Of tracts, thus separated by natural divisions, there are seventy-four, of which we shall only mention a few, Azia celebrated for the bravery of its people, and the valley of Nejran, renowned for the beauty of its site. This fertile region, lying between

## YEMEN.

inaccessible mountains, is watered by numerous streams, and is celebrated for the culture of dates and raisins, that obtain a ready sale all through Yemen. The aspect of this region is beautiful, the mountain to the very top being covered with luxuriant vegetation, and the valleys between offering the picture of a continuous garden. The principal town is Hamdan, and is about thirty days Journey from Mekkah. Of these subdivisions of Yemen, that of Sana is the most southerly, stretching even to the Arabian Sea, where it touches Aden.

The tract of country called Belad Aden commences at Bab-el-Mandel, and runs easterly along the coast a distance of 132 miles. This district is for the most part level, and inhabited by native Arab tribes. At about 90 miles from the western extremity, on a rocky promontory, stands the town of Aden. On the same or nearly the same site, there stood in ancient times, a city, well-known to the Greeks as the depot of the trade carried on between India and Egypt. This city was destroyed by the Romans in the first century of the Christian era, a deed of destruction said to have been prompted by the desire of keeping the Indian trade exclusively in Roman hands. As to ruin is easier than to reedify, we hear little of Aden until the eleventh century, when we find it again enjoying all the advantages which its position affords. Its commodious harbours were frequented by ships and the stream of commerce again flowed through the land. During a period of several hundred years, Aden enjoyed the supremacy amongst the ports of the coast, but the discovery of the passage to India, by the Cape of Good Hope, operated so injuriously on the Arabic city, that in a few years all traces of commercial prosperity departed, and the Turks were masters of Aden. Those were the palmy days of Ottoman power, and the military genius of the new conquerors of Aden showed itself in the erection of fortifications which resisted in the time of their strength, the attacks of some of the ablest European forces, and whose ruins long after excited the admiration of travellers. In 1839, Aden became a British possession, and so rapid were the advances in prosperity that the population which in 1839, amounted only to 1,000, had in 1842 risen to nearly twenty thousand.

Aden, is the principal coal station for steamers navigating the Red Sea, and has a good harbour. The little island of Sirah lying on the east side of the town, forms a bay opposite Aden, and from this point, the peninsula extends three miles westward, forming a commodious and safe harbour.

Many persons have found a resemblance between Aden and Gibraltar, a likeness dependent in a great measure on the rocky peninsula, which rising to a height of 1,700 feet, terminates in two points. The similarity is fully established

## ZAYAT.

in the scarcity of good water that prevails in both places. The great monarch, Soleiman the Magnificent, constructed an aqueduct at Aden, which commenced at a distance of eight miles from the town. The restoration of this aqueduct would, it is thought, supply the want so often felt at Aden. Of the importance of this station, we need not speak, and recent accounts show the imperative necessity of placing the English residents there, out of the power of hostile or mercenary tribes, who, under the influence of malice or avarice may at any time cut off the necessary supplies.

There are two caravan routes leading from Aden into the interior. Each pursues a different course for some distance, but both diverge considerably to arrive at the town of Lahaj, the capital of the Abdale Arabs. It is a dirty town, containing about 5,000 inhabitants, amongst whom are many Jews.

Having given this general description of the province of Yemen in the south of which the state of Aden lies, we shall turn to the southwest, where the straits of Bab-el-Mandel separate Arabia from Africa. These straits, which are between twenty and thirty miles in breadth, are celebrated amongst ancient writers for the dangers encountered by navigators who ventured within these gates of tears.

Perim lies about three miles distant from the Asiatic coast, thus, dividing the waters of the straits into two channels, that on the Asiatic side being narrower but deeper, and also free from the impediments offered by small islands, which are rather numerous on the African side. The entrance of a sea, traversed only by English ships, can be of importance to none but the nation to which these ships belong; any interference with the position we have taken, under such circumstances, must be regarded with a jealous eye.

(3046) YUDHISTHIRA, (kali yuga) its commencement 3101 B. C.

(3047) YOMA. A range of mountains in

## ZEEARUT.

Burmah, supposed to be the Meandrus of Ptolemy.

(3048) YU, *Chinese*. This mineral is supposed by most to be Jade, but Mr. Crawford calls it noble serpentine. It is found near the sources of the Oru, in a long narrow valley, and attracts Chinese traders to Mogoung, who purchase it for exportation to China where it fetches an extravagant price and is manufactured into cups, bracelets, &c. It is found in the form of boulders embedded in a yellow clay. It is of the Yu stone, that the Chinese form their waved emblem of longevity, specimens of which sometimes bring 100 dollars.

James Prinsep, too, considers that this mineral is prase, rather than jade. It is found in the valley of the Ooroo, and tributary of the Ningthe or Kyendwen, some fifty or sixty miles west of Mogoung. The mineral which is dug up by the Shans and Kakhyens, is found in the form of boulders embedded in yellow clay and the larger blocks are transported by means of bamboo frames, borne by four or five men. Both Crawford and Pemberton call this green, translucent and very hard mineral, noble serpentine. It is largely purchased by the Chinese in Burma for exportation to China, where, probably on account of some supposed talismanic or detective virtues, it fetches an extravagant price and is manufactured into cups, bracelets &c. Respectable Chinese at Amarapoora represent this trade as amounting to from six to ten lacs of tikals per annum. This is probably exaggerated; but the mineral is said to sell in China for twice its weight in silver. Dr. Bayfield was informed that the duty on the stone sometimes reached 40,000 Rupees a year. Captain Hannay, however, was told at Magoung that, including this duty, the revenue of the town and neighbouring villages did not exceed 30,000 rupees a year. The persons who come to make the purchases are Chinese Mahomedans.—*Yule's Embassy*, p. 147.

(3049) YURO, in Mindoro, is the heart or pith of the trunk of a palm, known by the name of Cabo negro.

## Z.

(3050) ZAFAR-NAMAH, the Persian name of a work, purporting to contain a conversation between Aristotle and Burzurjmihir.

(3051) ZAYAT, BURMESE. A public shed or portico, for the accommodation of travellers, loungers, and worshippers, found in every Burmese village and attached to many Pagodas. It corresponds to the *Dharm-sala* of northern and the choultry or chuttrum of Southern India. *Yule's Embassy*, p. 23.

(3052) ZEA MAYS. There are six or seven varieties of this. The American variety has been extensively distributed throughout the Himalayan hills and plains of the North West Provinces.—*Jameson's Report*.

(3053) ZEEARUT, ARAB. The visiting of the graves of deceased Mahomedans, on the third day after demise, which is called the "Teeja" meaning third day, when oblations are offered. *Herklots*.

## ZINC.

(3054) ZĒND, a language, in which the Parsee religious books were written by Zoroaster. According to Professor Bopp, the Zend is as old as the Vedas, is in many respects beyond and an improvement on the Sanscrit, and he does not admit it to be a mere dialect of the Zend, though some European authors contend that it is derived from the Sanscrit. The Zend seems to have been spoken in Bactria. Professor Rusk considers that the Zend was the spoken language of Media, and that the Vendidad, one of the books written in this language, was produced before the time of Alexander the Great. That it was the popular language of a great part of Iran. The author Masudi testifies that the books called Asta or Avasta and its commentary the Pazend were in existence in his time. While Rhode has come to the conclusion that the collection styled the Zend Avasta, contains either one or most of the compositions which existed before the destruction of the Persian empire by Alexander. The Zend and Pehlevi are believed by Anquetil du Perron, to have been authentic languages through the medium of which Zertusht on Zoroaster, in the Zendavista, handed down his religious system. Erskine, however, a great scholar, while he believes in the antiquity and authenticity of the Zend, holds that it was never a spoken language, but rather a composite of some peculiar dialect of Sanscrit and spoken Persian, made by the Parsee priests and used for the compilation of the Vendidad, which he believes to have been made about A. D. 229. One or other of these views have been held by Professors Romer; Rusk, Wilson, Bopp, Richardson; Lassen; Vans Kennedy and Sir William Jones who distinctly stated that the Zend had been fabricated by the Parsi priests, from many dialects: that its literature is worthless and that the whole dates no farther back than the Mahomedan conquest of Persia.—*The Parsees*, pages 247 &c.

(3055) ZINC MINES OF JAWAR. Captain J. C. BROOKE, of the *Mewar Bheel Corps*, states that the hilly country of Mēwar has always been known to abound in metalliferous ores, and it is supposed that the produce resulting therefrom was one of the sources of wealth, by which former Rānās of Udyapura, were enabled to contend successfully for so many years against the might and power of the Delhi emperors. The most celebrated of these mines and which were worked to the greatest advantage are undoubtedly those of Jāwar. On one occasion of visiting Jāwar, an old man brought a basket of the ore in its rough state. He described it as being found in veins 3 or 4 inches thick and sometimes in bunches, in quartz rock and mixed with other stone. He broke some pieces with a hammer, showing the good ore and the simple way it was freed from the quartz rock, with which

## ZOROASTER.

then pounded and freed from quartz and placed in crucibles some 8 or 9 inches high and 3 inches diameter; with necks 6 inches long and half an inch in diameter. The mouth being fastened up, the crucibles are inverted and placed in rows on a charcoal furnace when the ore is fused in about 3 or 4 hours. If pieces of the quartz are allowed to remain with the ore, the crucibles of course break. From each crucible the quantity of metal collected does not vary much.—*Beng. As. Soc. Journal*, No. III of 1850, p. 212.

(3056) ZINC, OXIDE OF; Zung-i-Basree. Pers.

(2057) ZONAR, The sacred cord, worn by the Hindoos, called 'zonar,' is regarded by the brahmins as of a highly mysterious and sacred import; and they do not consider an individual as fully member of his class until he have assumed this holy emblem. A brahmin should be invested with it at the age of eight years, by the hands of his father, who, with his tutor, twists that first put on. The zonar must be made by a brahmin: it is composed of three threads, each measuring ninety-six hands; they are twisted together, and folded into three, then twisted again, making it to consist of nine threads; these are again folded into three, without twisting, and each end fastened with a knot. It is put over the left shoulder, next the skin, and hangs down the right thigh as low as the fingers can reach. Of these zonars, a brahmin wears four; the other privileged tribes but three. Some writers call this the brahminical, or priestly, or sacerdotal thread; but not, it would appear, in strict correctness—it not being confined even to the priestly tribe, but worn by three out of the four tribes of Hindoos.—*More's Hindoo Pantheon*, quoted in *Chow-chow*, page 85.

(3058) ZOROASTER, SON OF PUROSHUP;—The lawgiver of the Persians, Zertusht, Zurtoht, Zerdusht or Zeratusht was born in the city of Rai, in Persia, and became known in the reign of king Gushtasp, Darius Hystaspes of the Greeks, the fifth king of the Kaianian dynasty, and who embraced the faith propounded by Zoroaster. Zoroaster is said to have been then of the age of forty, and to have appeared before Gustashp, in the thirtieth year of that monarch's reign, when he produced to the king the sacred books called Avasta, written in the Zend language. The religion commenced in the reign of Gushtasp, or Darius Hystaspes, from which time till the conquest of Persia by Alexander the Great, a period of three hundred years, it was in its most flourishing condition. From that time, the religion of Zoroaster continued to decline, till revived in A. D. 226 by Ardeshir Bakekan, Son of San or Artaxerxes, and the first of the Sassanian kings.

Before the advent of this teacher, the Persians were worshippers of idols, but the religion propounded by him is a theism recognising a Cre-

quetil du Perron, the first duty is to recognise and adore the master of all good, the Principle of all righteousness, Ormuzd, according to the prescribed form of worship, and with purity of thought, word, and action, and generally to honour Ormuzd (the Almighty as he is styled in the Avasta) in all that He has produced. The second point in the theology of the Parsees is to detest Ahriman, the author of all bad, moral and physical, his productions and works. God, according to Parsee theology, is the emblem of glory, refulgence, light, and in this view a Parsee while engaged in prayer stands before a fire or directs his face towards the Sun as the most proper symbol of the Almighty. The Sacred fires of the Parsee fire temples are attended day and night by Andiarvas or Priests and are never permitted to expire. They are preserved in a large chafing dish carefully supplied with fuel, perfumed by a small quantity of Sandal Wood or other aromatics: The illiterate adore this sacred flame, as also the sun, moon and stars, but the educated under the Symbol of fire adore the Almighty or Fountain of light, the author and dispenser of all things, the sun being merely regarded as a creature of the Creator which was to be revered as His best and fairest image, and for the numberless blessings it diffuses on the earth,—while the sacred flame of the fire temples was intended as a perpetual monitor to preserve their purity, of which this element is so expressive a Symbol. In the 16 Schlokes or distiches, which they prepared with a view to explain their religion to the Rana at Damaun, they (1) avowed their worship of a Supreme being (Ormuzd) and the sun and five elements; (2) preserving silence while bathing; praying; making offerings to fire and eating; (3) their use of incense, perfumes, and flowers in their religious ceremonies; (4) their worship of the cow; (5) their use of the *Sadra* or Shirt, as a sacred garment; and of the kusti or cincture for the loins and the cap of two folds;—(6) their use of songs and music in their marriages; (7) ornaments and perfumes by their wives; (8) their charity and excavating of tanks and wells; (9) their sympathy with men and women; (10) their use of *gaomutra* one of the excretions of the cow; (11) their wearing the sacred girdle at prayer and eating; (12) their feeding the sacred flame with incense; (13) their practice of devotion five times a day; (14) their conjugal fidelity and purity; (15) annual religious rites on behalf of ancestors; and (16) their placing great restraints on their women, after child birth.

When death is drawing near, prior to the flight of the soul, the body of the dying person is washed and arrayed in fine clothes. After death, the remains are placed on an oblong piece of polished stone, laid on the floor, and the following morning, generally, replaced on

*Zars* or corpse bearers, who after prayers by the priests, carry it to the Dokhma or tower of silence.

The Dokhma is erected in a solitary place: those in Bombay being on the most secluded and highest parts of Malabar hill. Arrived at this place, the iron bier is placed on the ground, and a last look of the dead allowed by uncovering the face, and then removed within the tower, where exposed to the vultures and other carnivorous birds it is soon denuded of flesh, the bones fall through the iron grating into a pit beneath, from which they are afterwards removed into a subterranean entrance made for that purpose. Parsees meeting a dead body of a member of their tribe, bow to it.

These religionists perform annual ceremonies in memory of the dead, but on the "Furrohur din jasan" are performed the sacred rites of the friends who have died in long voyages or the precise date of whose demise is not ascertained.

The first act of Parsees, on their occupying any locality, is to erect this place, and it is known from this that their first settlement in Bombay was about the year 1671.

After the Mahomedan conquest of Persia, the Parsees, being persecuted by the Arabs, fled to the mountains of Khorassan, where they found a shelter for about a hundred years, but, being again compelled to flee from their enemies, they emigrated to the little island of Ormuz at the mouth of the Persian Gulf, and subsequently, from the same cause they quitted Ormuz for the western coast of India. According to the Kissa Sanjan, they first landed on the small island of Diu or Diew, in the Gulf of Cambay, lying to the south west of the Peninsula of Katiwar, which after a short residence of 19 years they again quitted for Guzerat, and landed at Damaun in A. D. 717.

It was here, at Sanjan, in A. D. 721, that the Parsees erected the first fire temple and saw the sacred flame kindled on its altar. They remained here, in peace, for about 300 years, small communities settling in other towns in Guzerat, but all engaged in cultivation. But, in 1507, having engaged in the cause of a Hindoo prince who sustained a defeat, they quitted Sanjan for the mountains of Baharout taking with them the sacred fire, from which it was subsequently removed to Nowsaree, and lately, owing to disputes among the priests, it was secretly removed to Oodwara, 32 miles south of Surat, where it still exists, and being the oldest fire temple of the Zoroastrians in India, it is held in the highest veneration. The remnant of the Parsees in Persia, is now almost confined to the town of Yezd and the twenty-four surrounding villages, and in 1854, there were there one thousand families, comprising a population of 6,658 souls, of whom 3,310 were men and 3,348 were

## ZOROASTER.

tural pursuits. At Kirman the Parsees number about 450; in Teheran there are only about fifty merchants of this race. They have fire-temples but no ancient liturgical books.

The total number of this race of the present day, who are followers of Zoroaster, does not exceed 150,000 persons, and the census of the 20th August 1854 showed those of Bombay to amount to 110,544; of whom 68,754 were men and 41,790 were women.

More than half this number, viz. 61,298, of all this tribe in Bombay were merchants, bankers, or brokers.

In Western India they are a liberal minded and open handed race, and one of their number Sir Jamsetjee Jejeebhoy has given away sums, for public charities to the extent of £250,000.

## ZYE.

They have two sects, the Shensoys and Kudmis, whose only dissimilarity arises from their different mode of computing since 1746, the era of Yedezird which occasions a difference amongst the two sects in the time of celebrating their festivals. The numbers of the Shensoys ten times exceed those of the Kudmis.

It is a common notion that Parsees will not use fire arms, from their worshipping or venerating fire but this a mistake.—*The Parsees*, pages, 7, 8, 10, 12, 21, 25, 31, 37, 57, 61, 152, 236, 242, 259, 261.

(3058) ZYE, PUSHTOO. A term subjoined to several Affghan tribes, as the Ensoof Zye, the Baruk-Zye, and Hussain Zye.

THE END.
